## Foreword

This Technical Specification has been produced by the 3GPP.

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of this TS, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version 3.y.z

where:

- x the first digit:
  - 1 presented to TSG for information;
  - 2 presented to TSG for approval;
  - 3 Indicates TSG approved document under change control.
- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
- z the third digit is incremented when editorial only changes have been incorporated in the specification.

---

# 1 Scope

This specification describes the documents being produced by the 3GPP TSG RAN WG1 and first complete versions expected to be available by end of 1999. This specification describes the characteristics of the Layer 1 multiplexing and channel coding in the FDD mode of UTRA.

The 25.2 series specifies Um point for the 3G mobile system. This series defines the minimum level of specifications required for basic connections in terms of mutual connectivity and compatibility.

---

# 3 Definitions, symbols and abbreviations

## 3.1 Definitions

For the purposes of the present document, the [following] terms and definitions [given in ... and the following] apply.

**<defined term>**: <definition>.

- TG*: Transmission Gap is consecutive empty slots that have been obtained with a transmission time reduction method. The transmission gap can be contained in one or two consecutive radio frames.
- TGL*: Transmission Gap Length is the number of consecutive empty slots that have been obtained with a transmission time reduction method.  $0 \leq TGL \leq 14$

## 3.2 Symbols

For the purposes of the present document, the following symbols apply:

<symbol>      <Explanation>

$\hat{x}$  round towards  $\mathbb{Y}$ , i.e. integer such that  $x \leq \hat{x} < x+1$

$\check{x}$  round towards  $-\mathbb{Y}$ , i.e. integer such that  $x-1 < \check{x} \leq x$

$|x|$  absolute value of  $x$

$N_{first}$  The first slot in the  $TG$ .

$N_{last}$  The last slot in the  $TG$ .  $N_{last}$  is either a slot in the same radio frame as  $N_{first}$  or a slot in the radio frame immediately following the slot that contains  $N_{first}$ .

Unless otherwise is explicitly stated when the symbol is used, the meaning of the following symbols is:

$i$  TrCH number

$j$  TFC number

$k$  Bit number

$l$  TF number

$m$  Transport block number

$n_i$  Radio frame number of TrCH  $i$ .

$p$  PhCH number

$r$  Code block number

$I$  Number of TrCHs in a CCTrCH.

$C_i$  Number of code blocks in one TTI of TrCH  $i$ .

$F_i$  Number of radio frames in one TTI of TrCH  $i$ .

$M_i$  Number of transport blocks in one TTI of TrCH  $i$ .

$P$  Number of PhCHs used for one CCTrCH.

$PL$  Puncturing Limit for the uplink. Signalled from higher layers

$RM_i$  Rate Matching attribute for TrCH  $i$ . Signalled from higher layers.

Temporary variables, i.e. variables used in several (sub)sections with different meaning.

$x, X$

$y, Y$

$z, Z$

## 3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

<ACRONYM>    <Explanation>

ACS            Add, Compare, Select

ARQ            Automatic Repeat Request

BCH            Broadcast Channel

BER            Bit Error Rate

BLER          Block Error Rate

BS             Base Station

CCPCH        Common Control Physical Channel

CCTrCH      Coded Composite Transport Channel

CRC            Cyclic Redundancy Code

DCH            Dedicated Channel

DL             Downlink (Forward link)

DPCH         Dedicated Physical Channel

DPCCH        Dedicated Physical Control Channel

DPDCH        Dedicated Physical Data Channel

DS-CDMA     Direct-Sequence Code Division Multiple Access

DSCH         Downlink Shared Channel

DTX            Discontinuous Transmission

FACH	Forward Access Channel
FDD	Frequency Division Duplex
FER	Frame Error Rate
GF	Galois Field
MAC	Medium Access Control
Mcps	Mega Chip Per Second
MS	Mobile Station
OVSF	Orthogonal Variable Spreading Factor (codes)
PCCC	Parallel Concatenated Convolutional Code
PCH	Paging Channel
PRACH	Physical Random Access Channel
PhCH	Physical Channel
QoS	Quality of Service
RACH	Random Access Channel
RX	Receive
SCH	Synchronisation Channel
SF	Spreading Factor
SFN	System Frame Number
SIR	Signal-to-Interference Ratio
SNR	Signal to Noise Ratio
TF	Transport Format
TFC	Transport Format Combination
TFCI	Transport Format Combination Indicator
TPC	Transmit Power Control
TrCH	Transport Channel
TTI	Transmission Time Interval
TX	Transmit
UL	Uplink (Reverse link)

---

## 4 Multiplexing, channel coding and interleaving

### 4.1 General

Data stream from/to MAC and higher layers (Transport block / Transport block set) is encoded/decoded to offer transport services over the radio transmission link. Channel coding scheme is a combination of error detection, error correcting, rate matching, interleaving and transport channels mapping onto/splitting from physical channels.

### 4.2 Transport-channel coding/multiplexing

Data arrives to the coding/multiplexing unit in form of transport block sets once every transmission time interval. The transmission time interval is transport-channel specific from the set { 10 ms, 20 ms, 40 ms, 80 ms }.

The following coding/multiplexing steps can be identified:

- Add CRC to each transport block (see Section 4.2.1)
- Transport block concatenation and code block segmentation (see Section 4.2.2)
- Channel coding (see Section 4.2.3)
- Rate matching (see Section 4.2.7)
- Insertion of discontinuous transmission (DTX) indication bits (see Section 4.2.9)
- Interleaving (two steps, see Section 4.2.4 and 4.2.11)
- Radio frame segmentation (see Section 4.2.6)
- Multiplexing of transport channels (see Section 4.2.8)
- Physical channel segmentation (see Section 4.2.10)
- Mapping to physical channels (see Section 4.2.12)

The coding/multiplexing steps for uplink and downlink are shown in Figure 1 and Figure 2 respectively.

Figure 1: Transport channel multiplexing structure for uplink

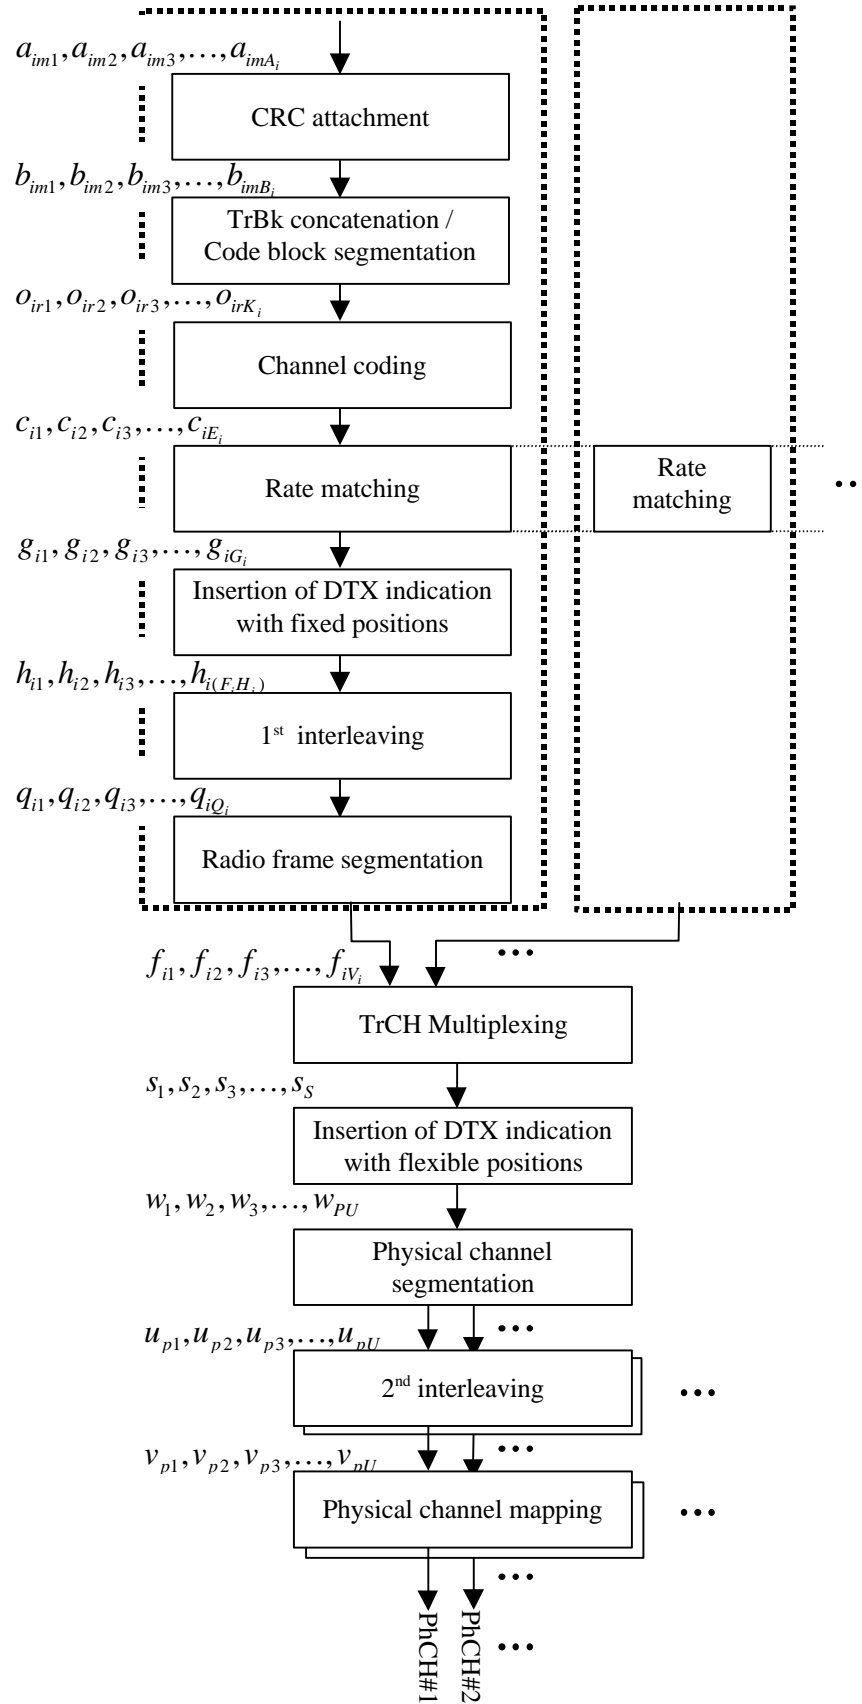

Figure 2: Transport channel multiplexing structure for downlink

The single output data stream from the TrCH multiplexing is denoted *Coded Composite Transport Channel (CCTrCH)*. A CCTrCH can be mapped to one or several physical channels.

## 4.2.1 Error detection

Error detection is provided on transport blocks through a Cyclic Redundancy Check. The CRC is 24, 16, 12, 8 or 0 bits and it is signalled from higher layers what CRC length that should be used for each TrCH.

### 4.2.1.1 CRC Calculation

The entire transport block is used to calculate the CRC parity bits for each transport block. The parity bits are generated by one of the following cyclic generator polynomials:

$$g_{\text{CRC24}}(D) = D^{24} + D^{23} + D^6 + D^5 + D + 1$$

$$g_{\text{CRC16}}(D) = D^{16} + D^{12} + D^5 + 1$$

$$g_{\text{CRC12}}(D) = D^{12} + D^{11} + D^3 + D^2 + D + 1$$

$$g_{\text{CRC8}}(D) = D^8 + D^7 + D^4 + D^3 + D + 1$$

Denote the bits in a transport block delivered to layer 1 by  $a_{im1}, a_{im2}, a_{im3}, \dots, a_{imA_i}$ , and the parity bits by  $p_{im1}, p_{im2}, p_{im3}, \dots, p_{imL_i}$ .  $A_i$  is the length of a transport block of TrCH  $i$ ,  $m$  is the transport block number, and  $L_i$  is 24, 16, 12, 8, or 0 depending on what is signalled from higher layers.

The encoding is performed in a systematic form, which means that in GF(2), the polynomial

$$a_{im1}D^{A_i+23} + a_{im2}D^{A_i+22} + \dots + a_{imA_i}D^{24} + p_{im1}D^{23} + p_{im2}D^{22} + \dots + p_{im23}D^1 + p_{im24}$$

yields a remainder equal to 0 when divided by  $g_{\text{CRC24}}(D)$ , polynomial

$$a_{im1}D^{A_i+15} + a_{im2}D^{A_i+14} + \dots + a_{imA_i}D^{16} + p_{im1}D^{15} + p_{im2}D^{14} + \dots + p_{im15}D^1 + p_{im16}$$

yields a remainder equal to 0 when divided by  $g_{\text{CRC16}}(D)$ , polynomial

$$a_{im1}D^{A_i+11} + a_{im2}D^{A_i+10} + \dots + a_{imA_i}D^{12} + p_{im1}D^{11} + p_{im2}D^{10} + \dots + p_{im11}D^1 + p_{im12}$$

yields a remainder equal to 0 when divided by  $g_{\text{CRC12}}(D)$  and polynomial

$$a_{im1}D^{A_i+7} + a_{im2}D^{A_i+6} + \dots + a_{imA_i}D^8 + p_{im1}D^7 + p_{im2}D^6 + \dots + p_{im7}D^1 + p_{im8}$$

yields a remainder equal to 0 when divided by  $g_{\text{CRC8}}(D)$ .

### 4.2.1.2 Relation between input and output of the Cyclic Redundancy Check

The bits after CRC attachment are denoted by  $b_{im1}, b_{im2}, b_{im3}, \dots, b_{imB_i}$ , where  $B_i = A_i + L_i$ . The relation between  $a_{imk}$  and  $b_{imk}$  is:

$$b_{imk} = a_{imk} \quad k = 1, 2, 3, \dots, A_i$$

$$b_{imk} = p_{im(L_i+1-(k-A_i))} \quad k = A_i + 1, A_i + 2, A_i + 3, \dots, A_i + L_i$$

## 4.2.2 Transport block concatenation and code block segmentation

All transport blocks in a TTI are serially concatenated. If the number of bits in a TTI is larger than  $Z$ , then code block segmentation is performed after the concatenation of the transport blocks. The maximum size of the code blocks depend on if convolutional or turbo coding is used for the TrCH.

### 4.2.2.1 Concatenation of transport blocks

The bits input to the transport block concatenation are denoted by  $b_{im1}, b_{im2}, b_{im3}, \dots, b_{imB_i}$  where  $i$  is the TrCH number,  $m$  is the transport block number, and  $B_i$  is the number of bits in each block (including CRC). The number of transport blocks on TrCH  $i$  is denoted by  $M_i$ . The bits after concatenation are denoted by  $x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$ , where  $i$  is the TrCH number and  $X_i = M_i B_i$ . They are defined by the following relations:

$$\begin{aligned} x_{ik} &= b_{i1k} & k &= 1, 2, \dots, B_i \\ x_{ik} &= b_{i,2,(k-B_i)} & k &= B_i + 1, B_i + 2, \dots, 2B_i \\ x_{ik} &= b_{i,3,(k-2B_i)} & k &= 2B_i + 1, 2B_i + 2, \dots, 3B_i \\ &\dots & & \\ x_{ik} &= b_{i,M_i,(k-(M_i-1)B_i)} & k &= (M_i - 1)B_i + 1, (M_i - 1)B_i + 2, \dots, M_i B_i \end{aligned}$$

### 4.2.2.2 Code block segmentation

Segmentation of the bit sequence from transport block concatenation is performed if  $X_i > Z$ . The code blocks after segmentation are of the same size. The number of code blocks on TrCH  $i$  is denoted by  $C_i$ . If the number of bits input to the segmentation,  $X_i$ , is not a multiple of  $C_i$ , filler bits are added to the last block. The filler bits are transmitted and they are always set to 0. The maximum code block sizes are:

convolutional coding:  $Z = 504$   
 turbo coding:  $Z = 5114$   
 no channel coding:  $Z = \text{unlimited}$

The bits output from code block segmentation are denoted by  $o_{ir1}, o_{ir2}, o_{ir3}, \dots, o_{irK_i}$ , where  $i$  is the TrCH number,  $r$  is the code block number, and  $K_i$  is the number of bits.

Number of code blocks:  $C_i = \lceil X_i / Z \rceil$   
 Number of bits in each code block:  $K_i = \lceil X_i / C_i \rceil$   
 Number of filler bits:  $Y_i = C_i K_i - X_i$

If  $X_i \leq Z$ , then  $o_{i1k} = x_{ik}$ , and  $K_i = X_i$ .

If  $X_i \geq Z$ , then

$$\begin{aligned} o_{i1k} &= x_{ik} & k &= 1, 2, \dots, K_i \\ o_{i2k} &= x_{i,(k+K_i)} & k &= 1, 2, \dots, K_i \\ o_{i3k} &= x_{i,(k+2K_i)} & k &= 1, 2, \dots, K_i \\ &\dots & & \\ o_{iC_i k} &= x_{i,(k+(C_i-1)K_i)} & k &= 1, 2, \dots, K_i - Y_i \\ o_{iC_i k} &= 0 & k &= (K_i - Y_i) + 1, (K_i - Y_i) + 2, \dots, K_i \end{aligned}$$

### 4.2.3 Channel coding

Code blocks are delivered to the channel coding block. They are denoted by  $o_{ir1}, o_{ir2}, o_{ir3}, \dots, o_{irK_i}$ , where  $i$  is the TrCH number,  $r$  is the code block number, and  $K_i$  is the number of bits in each code block. The number of code blocks on TrCH  $i$  is denoted by  $C_i$ . After encoding the bits are denoted by  $y_{ir1}, y_{ir2}, y_{ir3}, \dots, y_{irY_i}$ . The encoded blocks are serially multiplexed so that the block with lowest index  $r$  is output first from the channel coding block. The bits output are denoted by  $c_{i1}, c_{i2}, c_{i3}, \dots, c_{iE_i}$ , where  $i$  is the TrCH number and  $E_i = C_i Y_i$ . The output bits are defined by the following relations:

$$\begin{aligned} c_{ik} &= y_{i1k} & k &= 1, 2, \dots, Y_i \\ c_{ik} &= y_{i,2,k-Y_i} & k &= i \cdot 1, i \cdot 2, \dots, Y_i \\ c_{ik} &= y_{i,3,(k-2Y_i)} & k &= 2 \cdot i \cdot 1, 2Y_i + i, \dots, 3 \cdot i \end{aligned}$$

...

$$C_{ik} = y_{i,C_i,(k-(C_i-1)Y_i)} \quad k = (C_i - 1)Y_i + 1, (C_i - 1)Y_i + 2, \dots, C_iY_i$$

The relation between  $O_{irk}$  and  $y_{irk}$  and between  $K_i$  and  $Y_i$  is dependent on the channel coding scheme.

The following channel coding schemes can be applied to TrCHs:

- Convolutional coding
- Turbo coding
- No channel coding

The values of  $Y_i$  in connection with each coding scheme:

- Convolutional coding, 1/2 rate:  $Y_i = 2 * K_i + 16$ ; 1/3 rate:  $Y_i = 3 * K_i + 24$
- Turbo coding, 1/3 rate:  $Y_i = 3 * K_i + 12$
- No channel coding,  $Y_i = K_i$

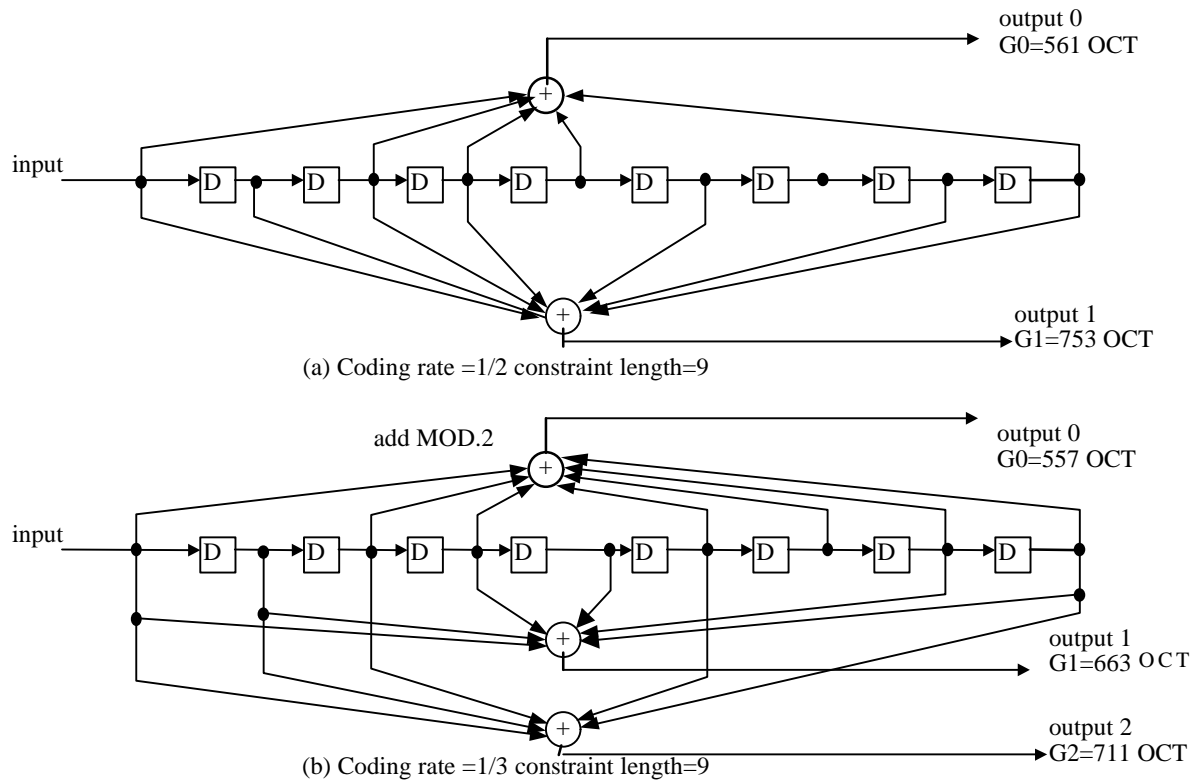

**Table 1: Error Correction Coding Parameters**

Transport channel type	Coding scheme	Coding rate
BCH	Convolutional code	1/2
PCH		
FACH		
RACH		1/3, 1/2 or no coding
CPCH		
DCH	Turbo Code	1/3 or no coding
CPCH		
DCH		

### 4.2.3.1 Convolutional coding

#### 4.2.3.1.1 Convolutional coder

- Constraint length  $K=9$ . Coding rate 1/3 and 1/2.
- The configuration of the convolutional coder is presented in Figure 3.
- The output from the convolutional coder shall be done in the order output0, output1, output2, output0, output1, ...,output2. (When coding rate is 1/2, output is done up to output 1).
- $K-1$  tail bits (value 0) shall be added to the end of the code block before encoding.
- The initial value of the shift register of the coder shall be "all 0".

**Figure 3: Convolutional Coder**

### 4.2.3.2 Turbo coding

#### 4.2.3.2.1 Turbo coder

For data services requiring quality of service between  $10^{-3}$  and  $10^{-6}$  BER inclusive, parallel concatenated convolutional code (PCCC) with 8-state constituent encoders is used.

The transfer function of the 8-state constituent code for PCCC is

$$G(D) = \left[ 1, \frac{n(D)}{d(D)} \right]$$

where,

$$d(D) = 1 + D^2 + D^3$$

$$n(D) = 1 + D + D^3$$

Figure 4: Structure of the 8 state PCCC encoder (dotted lines effective for trellis termination only)

The initial value of the shift registers of the PCCC encoder shall be all zeros.

The output of the PCCC encoder is punctured to produce coded bits corresponding to the desired code rate 1/3. For rate 1/3, none of the systematic or parity bits are punctured, and the output sequence is X(0), Y(0), Y'(0), X(1), Y(1), Y'(1), etc.

4.2.3.2.2 Trellis termination for Turbo coding

Trellis termination is performed by taking the tail bits from the shift register feedback after all information bits are encoded. Tail bits are added after the encoding of information bits.

The first three tail bits shall be used to terminate the first constituent encoder (upper switch of Figure 4 in lower position) while the second constituent encoder is disabled. The last three tail bits shall be used to terminate the second constituent encoder (lower switch of Figure 4 in lower position) while the first constituent encoder is disabled.

The transmitted bits for trellis termination shall then be

$$X(t) Y(t) X(t+1) Y(t+1) X(t+2) Y(t+2) X'(t) Y'(t) X'(t+1) Y'(t+1) X'(t+2) Y'(t+2).$$

4.2.3.2.3 Turbo code internal interleaver

Figure 5 depicts the overall 8 state PCCC Turbo coding scheme including Turbo code internal interleaver. The Turbo code internal interleaver consists of mother interleaver generation and pruning. For arbitrary given block length K, one mother interleaver is selected from the 134 mother interleavers set. The generation scheme of mother interleaver is described in section 4.2.3.2.3.1. After the mother interleaver generation, *l*-bits are pruned in order to adjust the mother interleaver to the block length K. The definition of *l* is shown in section 4.2.3.2.3.2.

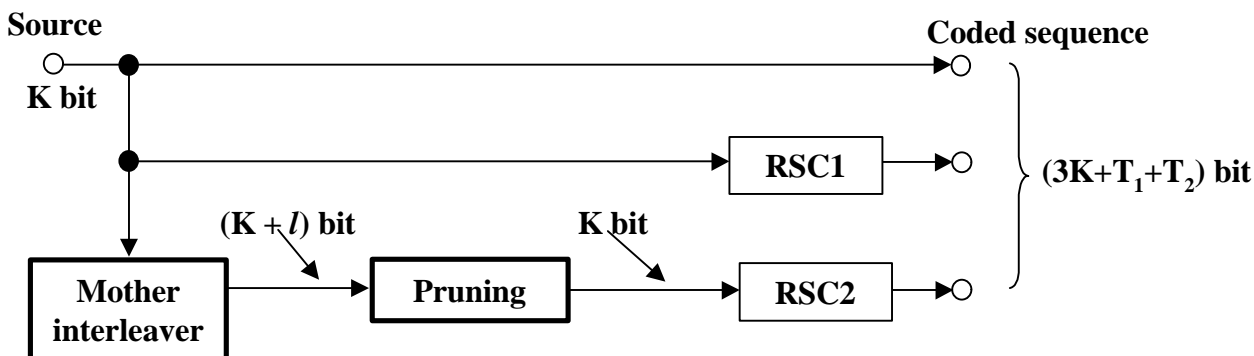

Figure 5: Overall 8 State PCCC Turbo Coding

## 4.2.3.2.3.1 Mother interleaver generation

The interleaving consists of three stages. In first stage, the input sequence is written into the rectangular matrix row by row. The second stage is intra-row permutation. The third stage is inter-row permutation. The three-stage permutations are described as follows, the input block length is assumed to be  $K$  (320 to 5114 bits).

**First Stage:**

- (1) Determine a row number  $R$  such that
  - $R=10$  ( $K = 481$  to  $530$  bits; Case-1)
  - $R=20$  ( $K =$  any other block length except  $481$  to  $530$  bits; Case-2)
- (2) Determine a column number  $C$  such that
  - Case-1;  $C = p = 53$
  - Case-2;
    - (i) find minimum prime  $p$  such that,
      - $0 \leq (p+1)-K/R$ ,
    - (ii) if  $(0 \leq p-K/R)$  then go to (iii),
      - else  $C = p+1$ .
    - (iii) if  $(0 \leq p-1-K/R)$  then  $C=p-1$ ,
      - else  $C = p$ .
- (3) The input sequence of the interleaver is written into the  $R \times C$  rectangular matrix row by row.

**Second Stage:****A. If  $C = p$** 

- (A-1) Select a primitive root  $g_0$  from Table 2.
- (A-2) Construct the base sequence  $c(i)$  for intra-row permutation as:
 
$$c(i) = [g_0 \times c(i-1)] \bmod p, i = 1, 2, \dots, (p-2), c(0) = 1.$$
- (A-3) Select the minimum prime integer set  $\{q_j\}$  ( $j=1, 2, \dots, R-1$ ) such that
  - $\text{g.c.d}\{q_j, p-1\} = 1$
  - $q_j > 6$
  - $q_j > q_{(j-1)}$
 where g.c.d. is greatest common divider. And  $q_0 = 1$ .
- (A-4) The set  $\{q_j\}$  is permuted to make a new set  $\{p_j\}$  such that
 
$$p_{P(j)} = q_j, j = 0, 1, \dots, R-1,$$
 where  $P(j)$  is the inter-row permutation pattern defined in the third stage.
- (A-5) Perform the  $j$ -th ( $j = 0, 1, 2, \dots, R-1$ ) intra-row permutation as:
 
$$c_j(i) = c([i \times p_j] \bmod (p-1)), \quad i = 0, 1, 2, \dots, (p-2), \text{ and } c_j(p-1) = 0,$$
 where  $c_j(i)$  is the input bit position of  $i$ -th output after the permutation of  $j$ -th row.

**B. If  $C = p+1$** 

- (B-1) Same as case A-1.
- (B-2) Same as case A-2.
- (B-3) Same as case A-3.
- (B-4) Same as case A-4.
- (B-5) Perform the  $j$ -th ( $j = 0, 1, 2, \dots, R-1$ ) intra-row permutation as:
 
$$c_j(i) = c([i \times p_j] \bmod (p-1)), \quad i = 0, 1, 2, \dots, (p-2), c_j(p-1) = 0, \text{ and } c_j(p) = p,$$
- (B-6) If  $(K = C \times R)$  then exchange  $c_{R-1}(p)$  with  $c_{R-1}(0)$ .
  - where  $c_j(i)$  is the input bit position of  $i$ -th output after the permutation of  $j$ -th row.

C. If  $C = p-1$

(C-1) Same as case A-1.

(C-2) Same as case A-2.

(C-3) Same as case A-3.

(C-4) Same as case A-4.

(C-5) Perform the  $j$ -th ( $j = 0, 1, 2, \dots, R-1$ ) intra-row permutation as:

$$c_j(i) = c([i \times p_j] \bmod (p-1)) - 1, \quad i = 0, 1, 2, \dots, (p-2),$$

where  $c_j(i)$  is the input bit position of  $i$ -th output after the permutation of  $j$ -th row.

**Third Stage:**

(1) Perform the inter-row permutation based on the following  $P(j)$  ( $j=0, 1, \dots, R-1$ ) patterns, where  $P(j)$  is the original row position of the  $j$ -th permuted row.

$P_A$ : {19, 9, 14, 4, 0, 2, 5, 7, 12, 18, 10, 8, 13, 17, 3, 1, 16, 6, 15, 11} for  $R=20$

$P_B$ : {19, 9, 14, 4, 0, 2, 5, 7, 12, 18, 16, 13, 17, 15, 3, 1, 6, 11, 8, 10} for  $R=20$

$P_C$ : {9, 8, 7, 6, 5, 4, 3, 2, 1, 0} for  $R=10$

The usage of these patterns is as follows:

Block length  $K$ :  $P(j)$

320 to 480-bit:  $P_A$

481 to 530-bit:  $P_C$

531 to 2280-bit:  $P_A$

2281 to 2480-bit:  $P_B$

2481 to 3160-bit:  $P_A$

3161 to 3210-bit:  $P_B$

3211 to 5114-bit:  $P_A$

(2) The output of the mother interleaver is the sequence read out column by column from the permuted  $R \times C$  matrix.

**Table 2: Table of prime  $p$  and associated primitive root**

$p$	$g_0$	$P$	$g_0$	$p$	$g_0$	$P$	$g_0$	$p$	$g_0$
17	3	59	2	103	5	157	5	211	2
19	2	61	2	107	2	163	2	223	3
23	5	67	2	109	6	167	5	227	2
29	2	71	7	113	3	173	2	229	6
31	3	73	5	127	3	179	2	233	3
37	2	79	3	131	2	181	2	239	7
41	6	83	2	137	3	191	19	241	7
43	3	89	3	139	2	193	5	251	6
47	5	97	5	149	2	197	2	257	3
53	2	101	2	151	6	199	3		

4.2.3.2.3.2 Definition of number of pruning bits

The output of the mother interleaver is pruned by deleting the  $l$ -bits in order to adjust the mother interleaver to the block length  $K$ , where the deleted bits are non-existent bits in the input sequence. The pruning bits number  $l$  is defined as:

$$l = R \times C - K,$$

where  $R$  is the row number and  $C$  is the column number defined in section 4.2.3.2.3.1.

### 4.2.4 Radio frame size equalisation

Radio frame size equalisation is padding the input bit sequence in order to ensure that the output can be segmented in  $F_i$  data segments of same size as described in section 4.2.6. Radio frame size equalisation is only performed in the UL (DL rate matching output block length is always an integer multiple of  $F_i$ )

The input bit sequence to the radio frame size equalisation is denoted by  $c_{i1}, c_{i2}, c_{i3}, \dots, c_{iE_i}$ , where  $i$  is TrCH number and  $E_i$  the number of bits. The output bit sequence is denoted by  $t_{i1}, t_{i2}, t_{i3}, \dots, t_{iT_i}$ , where  $T_i$  is the number of bits. The output bit sequence is derived as follows:

$$t_{ik} = c_{ik}, \text{ for } k = 1 \dots E_i \text{ and}$$

$$t_{ik} = \{0 \mid 1\} \text{ for } k = E_i + 1 \dots T_i, \text{ if } E_i < T_i$$

where

$$T_i = F_i * N_i \text{ and}$$

$$N_i = \lfloor (E_i - 1) / F_i \rfloor + 1 \text{ is the number of bits per segment after size equalisation.}$$

### 4.2.5 1<sup>st</sup> interleaving

The 1<sup>st</sup> interleaving is a block interleaver with inter-column permutations. The input bit sequence to the 1<sup>st</sup> interleaver is denoted by  $x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$ , where  $i$  is TrCH number and  $X_i$  the number of bits (at this stage  $X_i$  is assumed and guaranteed to be an integer multiple of TTI). The output bit sequence is derived as follows:

- (1) Select the number of columns  $C_I$  from Table 3.
- (2) Determine the number of rows  $R_I$  defined as

$$R_I = X_i / C_I$$

- (3) Write the input bit sequence into the  $R_I \times C_I$  rectangular matrix row by row starting with bit  $x_{i,1}$  in the first column of the first row and ending with bit  $x_{i,(R_I C_I)}$  in column  $C_I$  of row  $R_I$ :

$$\begin{bmatrix} x_{i1} & x_{i2} & x_{i3} & \dots & x_{iC_I} \\ x_{i,(C_I+1)} & x_{i,(C_I+2)} & x_{i,(C_I+3)} & \dots & x_{i,(2C_I)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ x_{i,((R_I-1)C_I+1)} & x_{i,((R_I-1)C_I+2)} & x_{i,((R_I-1)C_I+3)} & \dots & x_{i,(R_I C_I)} \end{bmatrix}$$

- (4) Perform the inter-column permutation based on the pattern  $\{P_1(j)\}$  ( $j=0,1, \dots, C-1$ ) shown in Table 3, where  $P_1(j)$  is the original column position of the  $j$ -th permuted column. After permutation of the columns, the bits are denoted by  $y_{ik}$ :

$$\begin{bmatrix} y_{i1} & y_{i,(R_I+1)} & y_{i,(2R_I+1)} & \dots & y_{i,((C_I-1)R_I+1)} \\ y_{i2} & y_{i,(R_I+2)} & y_{i,(2R_I+2)} & \dots & y_{i,((C_I-1)R_I+2)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ y_{iR_I} & y_{i,(2R_I)} & y_{i,(3R_I)} & \dots & y_{i,(C_I R_I)} \end{bmatrix}$$

- (5) Read the output bit sequence  $y_{i1}, y_{i2}, y_{i3}, \dots, y_{i,(C_I R_I)}$  of the 1<sup>st</sup> interleaving column by column from the inter-column permuted  $R_I \times C_I$  matrix. Bit  $y_{i,1}$  corresponds to the first row of the first column and bit  $y_{i,(R_I C_I)}$  corresponds to row  $R_I$  of column  $C_I$ .

Table 3

TTI	Number of columns $C_I$	Inter-column permutation patterns
10 ms	1	{0}
20 ms	2	{0,1}
40 ms	4	{0,2,1,3}
80 ms	8	{0,4,2,6,1,5,3,7}

#### 4.2.5.1 Relation between input and output of 1<sup>st</sup> interleaving in uplink

The bits input to the 1<sup>st</sup> interleaving are denoted by  $t_{i1}, t_{i2}, t_{i3}, \dots, t_{iT_i}$ , where  $i$  is the TrCH number and  $E_i$  the number of bits. Hence,  $x_{ik} = t_{ik}$  and  $X_i = T_i$ .

The bits output from the 1<sup>st</sup> interleaving are denoted by  $d_{i1}, d_{i2}, d_{i3}, \dots, d_{iT_i}$ , and  $d_{ik} = y_{ik}$ .

#### 4.2.5.2 Relation between input and output of 1<sup>st</sup> interleaving in downlink

If fixed positions of the TrCHs in a radio frame is used then the bits input to the 1<sup>st</sup> interleaving are denoted by  $h_{i1}, h_{i2}, h_{i3}, \dots, h_{i(F_i H_i)}$ , where  $i$  is the TrCH number. Hence,  $x_{ik} = h_{ik}$  and  $X_i = F_i H_i$ .

If flexible positions of the TrCHs in a radio frame is used then the bits input to the 1<sup>st</sup> interleaving are denoted by  $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$ , where  $i$  is the TrCH number. Hence,  $x_{ik} = g_{ik}$  and  $X_i = G_i$ .

The bits output from the 1<sup>st</sup> interleaving are denoted by  $q_{i1}, q_{i2}, q_{i3}, \dots, q_{iQ_i}$ , where  $i$  is the TrCH number and  $Q_i$  is the number of bits. Hence,  $q_{ik} = y_{ik}$ ,  $Q_i = F_i H_i$  if fixed positions are used, and  $Q_i = G_i$  if flexible positions are used.

### 4.2.6 Radio frame segmentation

When the transmission time interval is longer than 10 ms, the input bit sequence is segmented and mapped onto consecutive radio frames. Following rate matching in the DL and radio frame size equalisation in the UL the input bit sequence length is guaranteed to be an integer multiple of  $F_i$ .

The input bit sequence is denoted by  $x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$  where  $i$  is the TrCH number and  $X_i$  is the number bits. The  $F_i$  output bit sequences per TTI are denoted by  $y_{i,n_1}, y_{i,n_2}, y_{i,n_3}, \dots, y_{i,n_i}$  where  $n_i$  is the radio frame number in current TTI and  $Y_i$  is the number of bits per radio frame for TrCH  $i$ . The output sequences are defined as follows:

$$y_{i,n,k} = x_{i,((n-1)Y_i)+k}, n_i = 1 \dots F_i, j = 1 \dots Y_i$$

where

$Y_i = (X_i / F_i)$  is the number of bits per segment,

$x_{ik}$  is the  $k^{\text{th}}$  bit of the input bit sequence and

$y_{i,n,k}$  is the  $k^{\text{th}}$  bit of the output bit sequence corresponding to the  $n^{\text{th}}$  radio frame

The  $n_i$ -th segment is mapped to the  $n_i$ -th radio frame of the transmission time interval.

#### 4.2.6.1 Relation between input and output of the radio frame segmentation block in uplink

The input bit sequence to the radio frame segmentation is denoted by  $d_{i1}, d_{i2}, d_{i3}, \dots, d_{iT_i}$ , where  $i$  is the TrCH number and  $T_i$  the number of bits. Hence,  $x_{ik} = d_{ik}$  and  $X_i = T_i$ .

The output bit sequence corresponding radio frame  $n_i$  is denoted by  $e_{i1}, e_{i2}, e_{i3}, \dots, e_{iN_i}$ , where  $i$  is the TrCH number and  $N_i$  is the number of bits. Hence,  $e_{i,k} = y_{i,n_i,k}$  and  $N_i = Y_i$ .

#### 4.2.6.2 Relation between input and output of the radio frame segmentation block in downlink

The bits input to the radio frame segmentation are denoted by  $q_{i1}, q_{i2}, q_{i3}, \dots, q_{iQ_i}$ , where  $i$  is the TrCH number and  $Q_i$  the number of bits. Hence,  $x_{ik} = q_{ik}$  and  $X_i = Q_i$ .

The output bit sequence corresponding to radio frame  $n_i$  is denoted by  $f_{i1}, f_{i2}, f_{i3}, \dots, f_{iV_i}$ , where  $i$  is the TrCH number and  $V_i$  is the number of bits. Hence,  $f_{i,k} = y_{i,n_i,k}$  and  $V_i = Y_i$ .

### 4.2.7 Rate matching

Rate matching means that bits on a transport channel are repeated or punctured. Higher layers assign a rate-matching attribute for each transport channel. This attribute is semi-static and can only be changed through higher layer signalling. The rate-matching attribute is used when the number of bits to be repeated or punctured is calculated.

The number of bits on a transport channel can vary between different transmission time intervals. In the downlink the transmission is interrupted if the number of bits is lower than maximum. When the number of bits between different transmission time intervals in uplink is changed, bits are repeated or punctured to ensure that the total bit rate after second multiplexing is identical to the total channel bit rate of the allocated dedicated physical channels.

#### Notation used in Section 4.2.7 and subsections:

$N_{ij}$ : For uplink: Number of bits in a radio frame before rate matching on TrCH  $i$  with transport format combination  $j$ .

For downlink: An intermediate calculation variable (not a integer but a multiple of 1/8).

$N_{il}^{TTI}$ : Number of bits in a transmission time interval before rate matching on TrCH  $i$  with transport format  $l$ . Used in downlink only.

$\Delta N_{ij}$ : For uplink: If positive - number of bits that should be repeated in each radio frame on TrCH  $i$  with transport format combination  $j$ .

If negative - number of bits that should be punctured in each radio frame on TrCH  $i$  with transport format combination  $j$ .

For downlink: An intermediate calculation variable (not integer but a multiple of 1/8).

$\Delta N_{il}^{TTI}$ : If positive - number of bits to be repeated in each transmission time interval on TrCH  $i$  with transport format  $j$ .

If negative - number of bits to be punctured in each transmission time interval on TrCH  $i$  with transport format  $j$ .

Used in downlink only.

$RM_i$ : Semi-static rate matching attribute for transport channel  $i$ . Signalled from higher layers.

$PL$ : Puncturing limit for uplink. This value limits the amount of puncturing that can be applied in order to avoid multicode or to enable the use of a higher spreading factor. Signalled from higher layers.

$N_{data,j}$ : Total number of bits that are available for the CCTrCH in a radio frame with transport format combination  $j$ .

$I$ : Number of TrCHs in the CCTrCH.

$Z_{ij}$ : Intermediate calculation variable.

$F_i$ : Number of radio frames in the transmission time interval of TrCH  $i$ .

$n_i$ : Radio frame number in the transmission time interval of TrCH  $i$  ( $0 \leq n_i < F_i$ ).

- $q$ : Average puncturing distance. Used in uplink only.
- $I_F(n_i)$ : The inverse interleaving function of the 1<sup>st</sup> interleaver (note that the inverse interleaving function is identical to the interleaving function itself for the 1<sup>st</sup> interleaver). Used in uplink only.
- $S(n_i)$ : The shift of the puncturing pattern for radio frame  $n_i$ . Used in uplink only.
- $TF_i(j)$ : Transport format of TrCH  $i$  for the transport format combination  $j$ .
- $TFS(i)$  The set of transport format indexes  $l$  for TrCH  $i$ .
- $TFCS$  The set of transport format combination indexes  $j$ .
- $e_{ini}$  Initial value of variable  $e$  in the rate matching pattern determination algorithm of section 4.2.7.4.
- $e_{plus}$  Increment of variable  $e$  in the rate matching pattern determination algorithm of section 4.2.7.4.
- $e_{minus}$  Decrement of variable  $e$  in the rate matching pattern determination algorithm of section 4.2.7.4.
- $X$ : Systematic bit in section 4.2.3.2.1.
- $Y$ : 1<sup>st</sup> parity bit (from the upper Turbo constituent encoder) in section 4.2.3.2.1.
- $Y'$ : 2<sup>nd</sup> parity bit (from the lower Turbo constituent encoder) in section 4.2.3.2.1.

Note: Time index  $t$  in section 4.2.3.2.1 is omitted for simplify the rate matching description.

The \* (star) notation is used to replace an index  $x$  when the indexed variable  $X_x$  does not depend on the index  $x$ . In the left wing of an assignment the meaning is that “ $X_* = Y$ ” is equivalent to “**for all**  $x$  **do**  $X_x = Y$ ”. In the right wing of an assignment, the meaning is that “ $Y = X_*$ ” is equivalent to “**take any**  $x$  **and do**  $Y = X_x$ ”

The following relations, defined for all TFC  $j$ , are used when calculating the rate matching parameters:

$$Z_{0,j} = 0$$

$$Z_{ij} = \left[ \frac{\sum_{m=1}^i RM_m \cdot N_{mj}}{\sum_{m=1}^I RM_m \cdot N_{mj}} \cdot N_{data,j} \right] \text{ for all } i = 1 .. I \quad (1)$$

$$\Delta N_{ij} = Z_{ij} - Z_{i-1,j} - N_{ij} \quad \text{for all } i = 1 .. I$$

#### 4.2.7.1 Determination of rate matching parameters in uplink

##### 4.2.7.1.1 Determination of SF and number of PhCHs needed

In uplink puncturing can be used to avoid multicode or to enable the use of a higher spreading factor when this is needed because the UE does not support SF down to 4. The maximum amount of puncturing that can be applied is signalled from higher layers and denoted by  $PL$ . The number of available bits in the radio frames for all possible spreading factors is given in [2]. Denote these values by  $N_{256}$ ,  $N_{128}$ ,  $N_{64}$ ,  $N_{32}$ ,  $N_{16}$ ,  $N_8$ , and  $N_4$ , where the index refers to the spreading factor. The possible values of  $N_{data}$  then are  $\{ N_{256}, N_{128}, N_{64}, N_{32}, N_{16}, N_8, N_4, 2N_4, 3N_4, 4N_4, 5N_4, 6N_4 \}$ . Depending on the UE capabilities, the supported set of  $N_{data}$ , denoted SET0, can be a subset of  $\{ N_{256}, N_{128}, N_{64}, N_{32}, N_{16}, N_8, N_4, 2N_4, 3N_4, 4N_4, 5N_4, 6N_4 \}$ .  $N_{data,j}$  for the transport format combination  $j$  is determined by executing the following algorithm:

$$SET1 = \{ N_{data} \text{ in SET0 such that } N_{data} - \sum_{x=1}^I \frac{RM_x}{\min_{1 \leq y \leq I} \{ RM_y \}} \cdot N_{x,j} \text{ is non negative} \}$$

If SET1 is not empty and the smallest element of SET1 requires just one PhCH then

$$N_{data,j} = \min SET1$$

else

$$\text{SET2} = \{ N_{data} \text{ in SET0 such that } N_{data} - PL \cdot \sum_{x=1}^I \frac{RM_x}{\min_{1 \leq y \leq I} \{RM_y\}} \cdot N_{x,j} \text{ is non negative} \}$$

Sort SET2 in ascending order

$$N_{data} = \min \text{ SET2}$$

While  $N_{data}$  is not the max of SET2 and the follower of  $N_{data}$  requires no additional PhCH do

$$N_{data} = \text{follower of } N_{data} \text{ in SET2}$$

End while

$$N_{data,j} = N_{data}$$

End if

#### 4.2.7.1.2 Determination of parameters needed for calculating the rate matching pattern

The number of bits to be repeated or punctured,  $DN_{ij}$ , within one radio frame for each TrCH  $i$  is calculated with equation 1 for all possible transport format combinations  $j$  and selected every radio frame.  $N_{data,j}$  is given from section 4.2.7.1.1. In compressed mode  $N_{data,j}$  is replaced by  $N_{data,j}^{cm}$  in Equation 1.  $N_{data,j}^{cm}$  is given from the following relation:

$$N_{data,j}^{cm} = 2N_{data,j} - N_{TGL}, \text{ where}$$

$$N_{TGL} = \begin{cases} \frac{TGL}{15} 2N_{data,j}, & \text{if } N_{first} + TGL \leq 15 \\ \frac{15 - N_{first}}{15} 2N_{data,j}, & \text{in first frame if } N_{first} + TGL > 15 \\ \frac{TGL - (15 - N_{first})}{15} 2N_{data,j}, & \text{in second frame if } N_{first} + TGL > 15 \end{cases}$$

$N_{first}$  and  $TGL$  are defined in Section 4.4.

If  $DN_{ij} = 0$  then the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.4 does not need to be executed.

Otherwise, for determining  $e_{ini}$ ,  $e_{plus}$ ,  $e_{minus}$ , and  $N$  the following parameters are needed (regardless if the radio frame is compressed or not):

For convolutional codes,

$$q = \mathbf{\bar{e}}N_{ij}/(\mathbf{\bar{O}}DN_{ij}\mathbf{\bar{O}})\mathbf{\bar{u}}$$

if  $q$  is even

$$\text{then } q' = q - \text{gcd}(q, F_i)/F_i \text{ -- where } \text{gcd}(q, F_i) \text{ means greatest common divisor of } q \text{ and } F_i$$

-- note that  $q'$  is not an integer, but a multiple of 1/8

else

$$q' = q$$

endif

for  $x = 0$  to  $F_i - 1$

$$S(I_F(\mathbf{\bar{e}}x * q' \mathbf{\bar{u}} \bmod F_i)) = (\mathbf{\bar{e}}x * q' \mathbf{\bar{u}} \text{ div } F_i)$$

end for

$$DN = DN_{i,j}$$

$$a = 2$$

For each radio frame, the rate-matching pattern is calculated with the algorithm in Section 4.2.7.4, where :

$$N = N_{i,j}, \text{ and}$$

$$e_{ini} = (a \times \lfloor DN \rfloor + N) \bmod a \times N, \text{ if } e_{ini} = 0 \text{ then } e_{ini} = a \times N.$$

$$e_{plus} = a \times N$$

$$e_{minus} = a \times \lfloor DN \rfloor$$

puncturing for  $DN < 0$ , repeating otherwise.

For turbo codes, if repetition is to be performed, such as  $DN_{i,j} > 0$ , parameters for turbo codes are the same as parameter for convolutional codes.

If puncturing is to be performed, parameters are as follows.

$a=2$  for Y sequence, and

$a=1$  for Y' sequence.

$$DN = \begin{cases} \lfloor DN_{i,j} / 2 \rfloor & \text{for Y sequence} \\ \lfloor DN_{i,j} / 2 \rfloor & \text{for Y' sequence} \end{cases}$$

$$N = \lceil DN_{i,j} / 3 \rceil \hat{u},$$

$$q = \lceil DN / DN \rceil \hat{u}$$

if( $q \leq 2$ )

for  $x=0$  to  $F_i-1$

if(Y sequence)

$$S[I_F[(3x+1) \bmod F_i]] = x \bmod 2;$$

if(Y' sequence)

$$S[I_F[(3x+2) \bmod F_i]] = x \bmod 2;$$

end for

else

if  $q$  is even

then  $q' = q - \gcd(q, F_i) / F_i$  -- where  $\gcd(q, F_i)$  means greatest common divisor of  $q$  and  $F_i$

-- note that  $q'$  is not an integer, but a multiple of  $1/8$

else  $q' = q$

endif

for  $x=0$  to  $F_i - 1$

$$r = \lceil x * q' \rceil \hat{u} \bmod F_i;$$

if(Y sequence)

$$S[I_F[(3r+1) \bmod F_i]] = \lceil x * q' \rceil \hat{u} \bmod F_i;$$

if(Y' sequence)

$$S[I_F[(3r+2) \bmod F_i]] = \lceil x * q' \rceil \hat{u} \bmod F_i;$$

endfor

endif

For each radio frame, the rate-matching pattern is calculated with the algorithm in section 4.2.7.4, where:

$N$  is as above,

$$e_{ini} = (a \times \mathcal{S}(n_i) \times |DN| + N) \bmod a \times N, \text{ if } e_{ini} = 0 \text{ then } e_{ini} = a \times N.$$

$$e_{plus} = a \cdot N$$

$$e_{minus} = a \times |DN|$$

puncturing for  $DN < 0$ , repeating otherwise.

#### 4.2.7.2 Determination of rate matching parameters in downlink

For downlink  $N_{data,j}$  does not depend on the transport format combination  $j$ .  $N_{data,*}$  is given by the channelization code(s) assigned by higher layers.

##### 4.2.7.2.1 Determination of rate matching parameters for fixed positions of TrCHs

First an intermediate calculation variable  $N_{i,*}$  is calculated for all transport channels  $i$  by the following formula :

$$N_{i,*} = \frac{1}{F_i} \cdot \max_{l \in TFS(i)} N_{i,l}^{TTI}$$

The computation of the  $\Delta N_{i,l}^{TTI}$  parameters is then performed in for all TrCH  $i$  and all TF  $l$  by the following formula, where  $\Delta N_{i,*}$  is derived from  $N_{i,*}$  by the formula given at section 4.2.7:

$$\Delta N_{i,*}^{TTI} = F_i \cdot \Delta N_{i,*}$$

If  $\Delta N_{i,*}^{TTI} = 0$  then, for TrCH  $i$ , the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.4 does not need to be executed.

Otherwise, for determining  $e_{ini}$ ,  $e_{plus}$ ,  $e_{minus}$ , and  $N$  the following parameters are needed:

For convolutional codes,

$$\Delta N = \Delta N_{i,*}^{TTI}$$

$$a=2$$

$$N_{max} = \max_{l \in TFS(i)} N_{il}^{TTI}$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in Section 4.2.7.4. The following parameters are used as input:

$$N = N_{il}^{TTI}$$

$$e_{ini} = N_{max}$$

$$e_{plus} = a \cdot N_{max}$$

$$e_{minus} = a \cdot |\Delta N|$$

Puncturing if  $\Delta N < 0$ , repetition otherwise.

For turbo codes, if repetition is to be performed, such as  $\Delta N_{i,*}^{TTI} > 0$ , parameters for turbo codes are the same as

parameter for convolutional codes. If puncturing is to be performed, parameters are as follows.

$a=2$  for  $Y$  sequence,

$a=1$  for  $Y'$  sequence.

The  $X$  bits shall not be punctured.

$$DN = \begin{cases} \lfloor DN_{i,*}^{TTI} / 2 \rfloor & \text{for } Y \text{ sequence} \\ \lfloor DN_{i,*}^{TTI} / 2 \rfloor & \text{for } Y' \text{ sequence} \end{cases}$$

$$N_{max} = \max_{l \in TFS(i)} \lfloor N_{il}^{TTI} / 3 \rfloor$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in Section 4.2.7.4. The following parameters are used as input:

$$N = \lfloor N_{il}^{TTI} / 3 \rfloor$$

$$e_{ini} = N_{max}$$

$$e_{plus} = a \cdot N_{max}$$

$$e_{minus} = a \cdot |\Delta N|$$

Puncturing if  $\Delta N < 0$ , repetition otherwise.

#### 4.2.7.2.2 Determination of rate matching parameters for flexible positions of TrCHs

First an intermediate calculation variable  $N_{ij}$  is calculated for all transport channels  $i$  and all transport format combinations  $j$  by the following formula :

$$N_{i,j} = \frac{1}{F_i} \cdot N_{i,TF_i(j)}^{TTI}$$

Then rate matching ratios  $RF_i$  are calculated for each the transport channel  $i$  in order to minimise the number of DTX bits when the bit rate of the CCTrCH is maximum. The  $RF_i$  ratios are defined by the following formula :

$$RF_i = \frac{N_{data,*}}{\max_{j \in TFCS} \sum_{i=1}^{i=I} (RM_i \cdot N_{i,j})} \cdot RM_i$$

The computation of  $\Delta N_{i,l}^{TTI}$  parameters is then performed in two phases. In a first phase, tentative temporary values of  $\Delta N_{i,l}^{TTI}$  are computed, and in the second phase they are checked and corrected. The first phase, by use of the  $RF_i$  ratios, ensures that the number of DTX indication bits inserted is minimum when the CCTrCH bit rate is maximum, but it does not ensure that the maximum CCTrCH bit rate is not greater than  $N_{data,*}$  per 10ms. The latter condition is ensured through the checking and possible corrections carried out in the second phase.

At the end of the second phase, the latest value of  $\Delta N_{i,l}^{TTI}$  is the definitive value.

The first phase defines the tentative temporary  $\Delta N_{i,l}^{TTI}$  for all transport channel  $i$  and any of its transport format  $l$  by use of the following formula :

$$\Delta N_{i,l}^{TTI} = F_i \cdot \left\lceil \frac{RF_i \cdot N_{i,l}^{TTI}}{F_i} \right\rceil - N_{i,l}^{TTI}$$

The second phase is defined by the following algorithm :

```

for all  $j$  in  $TFCS$  do                                -- for all TFC
     $D = \sum_{i=1}^{I} \frac{N_{i,TF_i(j)}^{TTI} + \Delta N_{i,TF_i(j)}^{TTI}}{F_i}$     -- CCTrCH bit rate (bits per 10ms) for TFC  $l$ 
    if  $D > N_{data,*}$  then
        for  $i = 1$  to  $I$  do                                -- for all TrCH
             $\Delta N = F_i \cdot \Delta N_{i,j}$                 --  $\Delta N_{i,j}$  is derived from  $N_{i,j}$  by the formula given at section 4.2.7
            if  $\Delta N_{i,TF_i(j)}^{TTI} > \Delta N$  then
                 $\Delta N_{i,TF_i(j)}^{TTI} = \Delta N$ 
            end-if
        end-for
    end-if
end-for
    
```

Note : the order in which the transport format combinations are checked does not change the final result.

If  $\Delta N_{i,l}^{TTI} = 0$  then, for TrCH  $i$  at TF  $l$ , the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.4 does not need to be executed.

Otherwise, for determining  $e_{ini}$ ,  $e_{plus}$ ,  $e_{minus}$ , and  $N$  the following parameters are needed:

For convolutional codes,

$$\Delta N = \Delta N_{il}^{TTI}$$

$$a=2$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in Section 4.2.7.4. The following parameters are used as input:

$$N = N_{il}^{TTI}$$

$$e_{ini} = N$$

$$e_{plus} = a \cdot N$$

$$e_{minus} = a \cdot |\Delta N|$$

puncturing for  $\Delta N < 0$ , repeating otherwise.

For turbo codes, if repetition is to be performed, such as  $\Delta N_{il}^{TTI} > 0$ , parameters for turbo codes are the same as parameter for convolutional codes. If puncturing is to be performed, parameters are as follows.

$a=2$  for  $Y$  sequence,  
 $a=1$  for  $Y'$  sequence.

$X$  bits shall not be punctured.

$$DN = \begin{cases} \left\lfloor DN_{il}^{TTI} / 2 \right\rfloor & \text{for } Y \text{ sequence} \\ \left\lfloor DN_{il}^{TTI} / 2 \right\rfloor & \text{for } Y' \text{ sequence} \end{cases}$$

For each transmission time interval of TrCH  $i$  with TF  $l$ , the rate-matching pattern is calculated with the algorithm in Section 4.2.7.4. The following parameters are used as input:

$$N = \lfloor N_{il}^{TTI} / 3 \rfloor,$$

$$e_{ini} = N,$$

$$e_{plus} = a \cdot N$$

$$e_{minus} = a \cdot |\Delta N|$$

puncturing for  $\Delta N < 0$ , repeating otherwise.

### 4.2.7.3 Bit separation for rate matching

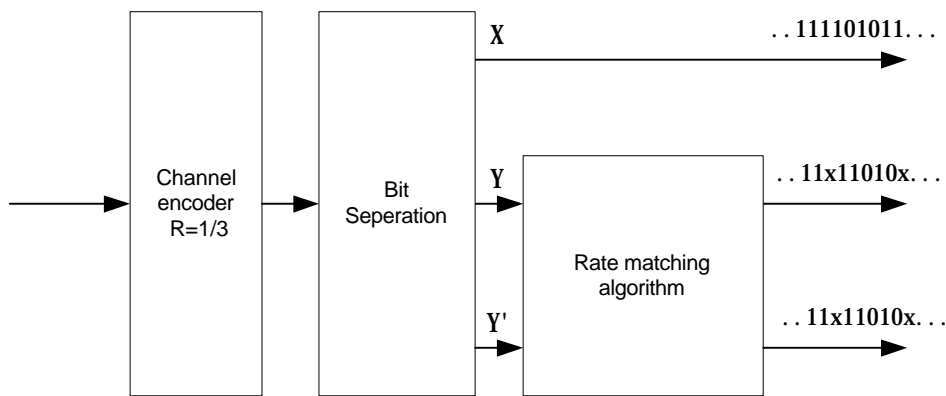

Figure 6: Overall rate matching block diagram before first interleaving where x denotes punctured bit.

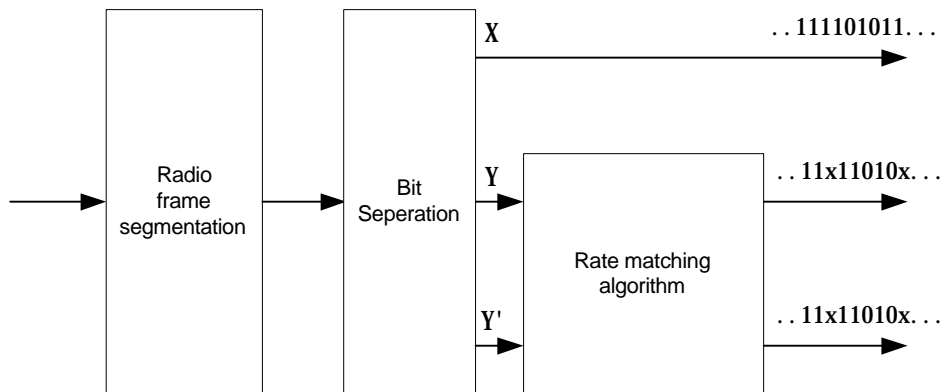

Figure 7: Overall rate matching block diagram after first interleaving where x denotes punctured bit.

Rate matching puncturing for Turbo codes in uplink is applied separately to  $Y$  and  $Y'$  sequences. No puncturing is applied to  $X$  sequence. Therefore, it is necessary to separate  $X$ ,  $Y$ , and  $Y'$  sequences before rate matching is applied.

For uplink, there are two different alternation patterns in bit stream from radio frame segmentation according to the TTI of a TrCH as shown in Table 4.

Table 4: Alternation patterns of bits from radio frame segmentation in uplink

TTI (msec)	Alternation patterns
10, 40	... X,Y,Y',...
20, 80	... X,Y',Y,...

In addition, each radio frame of a TrCH starts with different initial parity type. Table 5 shows the initial parity type of each radio frame of a TrCH with TTI = {10, 20, 40, 80} msec.

**Table 5: Initial parity type of radio frames of TrCH in uplink**

TTI (msec)	Radio frame indexes ( $n_i$ )							
	0	1	2	3	4	5	6	7
10	X	NA	NA	NA	NA	NA	NA	NA
20	X	Y	NA	NA	NA	NA	NA	NA
40	X	Y'	Y	X	NA	NA	NA	NA
80	X	Y	Y'	X	Y	Y'	X	Y

Table 4 and Table 5 defines a complete output bit pattern from radio frame segmentation.

Ex. 1. TTI = 40 msec,  $n_i = 2$

Radio frame pattern: Y, Y', X, Y, Y', X, Y, Y', X, ...

Ex. 2 TTI = 40 msec,  $n_i = 3$

Radio frame pattern: X, Y, Y', X, Y, Y', X, Y, Y', X, ...

Therefore, bit separation is achieved with the alternative selection of bits with the initial parity type and alternation pattern specified in Table 4 and Table 5 according to the TTI and  $n_i$  of a TrCH.

Rate matching puncturing for Turbo codes in downlink is applied separately to Y and Y's sequences. No puncturing is applied to X sequence. Therefore, it is necessary to separate X, Y, and Y' sequences before rate matching is applied.

For downlink, output bit sequence pattern from Turbo encoder is always X, Y, Y', X, Y, Y', .... Therefore, bit separation is achieved with the alternative selection of bits from Turbo encoder.

#### 4.2.7.4 Rate matching pattern determination

Denote the bits before rate matching by:

$x_{i1}, x_{i2}, x_{i3}, \dots, x_{iN}$ , where  $i$  is the TrCH number and  $N$  is the parameter given in section 4.2.7.2.

The rate matching rule is as follows:

if puncturing is to be performed

$e = e_{ini}$  -- initial error between current and desired puncturing ratio

$m = 1$  -- index of current bit

do while  $m \leq N$

$e = e - e_{minus}$  -- update error

if  $e \leq 0$  then -- check if bit number  $m$  should be punctured

puncture bit  $x_{i,m}$

$e = e + e_{plus}$  -- update error

end if

$m = m + 1$  -- next bit

end do

else

$e = e_{ini}$  -- initial error between current and desired puncturing ratio

$m = 1$  -- index of current bit

```

do while  $m \leq N$ 
     $e = e - e_{minus}$       -- update error
    do while  $e \leq 0$       -- check if bit number  $m$  should be repeated
        repeat bit  $x_{i,m}$ 
         $e = e + e_{plus}$  -- update error
    end do
     $m = m + 1$           -- next bit
end do
end if

```

A repeated bit is placed directly after the original one.

#### 4.2.7.5 Relation between input and output of the rate matching block in uplink

The bits input to the rate matching are denoted by  $e_{i1}, e_{i2}, e_{i3}, \dots, e_{iN_i}$ , where  $i$  is the TrCH.

Hence,  $x_{ik} = e_{ik}$  and  $N = N_{ij} = N_i$ .

The bits output from the rate matching are denoted by  $f_{i1}, f_{i2}, f_{i3}, \dots, f_{iV_i}$ , where  $i$  is the TrCH number and  $V_i = N + \Delta N = N_{ij} + \Delta N_{ij}$ .

Note that the transport format combination number  $j$  for simplicity has been left out in the bit numbering.

#### 4.2.7.6 Relation between input and output of the rate matching block in downlink

The bits input to the rate matching are denoted by  $c_{i1}, c_{i2}, c_{i3}, \dots, c_{iE_i}$ , where  $i$  is the TrCH number and  $l$  the transport format number. Hence,  $x_{ik} = e_{ik}$  and  $N = N_{il}^{TTI} = E_i$ .

The bits output from the rate matching are denoted by  $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$ , where  $i$  is the TrCH number and  $G_i = N + \Delta N = N_{il}^{TTI} + \Delta N_{il}^{TTI}$ .

Note that the transport format number  $l$  for simplicity has been left out in the bit numbering.

### 4.2.8 TrCH multiplexing

Every 10 ms, one radio frame from each TrCH is delivered to the TrCH multiplexing. These radio frames are serially multiplexed into a coded composite transport channel (CCTrCH).

The bits input to the TrCH multiplexing are denoted by  $f_{i1}, f_{i2}, f_{i3}, \dots, f_{iV_i}$ , where  $i$  is the TrCH number and  $V_i$  is the number of bits in the radio frame of TrCH  $i$ . The number of TrCHs is denoted by  $I$ . The bits output from TrCH multiplexing are denoted by  $s_1, s_2, s_3, \dots, s_S$ , where  $S$  is the number of bits, i.e.  $S = \sum_i V_i$ . The TrCH multiplexing

is defined by the following relations:

$$\begin{aligned}
 s_k &= f_{1k} & k &= 1, 2, \dots, V_1 \\
 s_k &= f_{2,(k-V_1)} & k &= V_1+1, V_1+2, \dots, V_1+V_2 \\
 s_k &= f_{3,(k-(V_1+V_2))} & k &= (V_1+V_2)+1, (V_1+V_2)+2, \dots, (V_1+V_2)+V_3 \\
 &\dots & & \\
 s_k &= f_{I,(k-(V_1+V_2+\dots+V_{I-1}))} & k &= (V_1+V_2+\dots+V_{I-1})+1, (V_1+V_2+\dots+V_{I-1})+2, \dots, (V_1+V_2+\dots+V_{I-1})+V_I
 \end{aligned}$$

## 4.2.9 Insertion of discontinuous transmission (DTX) indication bits

In the downlink, DTX is used to fill up the radio frame with bits. The insertion point of DTX indication bits depends on whether fixed or flexible positions of the TrCHs in the radio frame are used. It is up to the UTRAN to decide for each CCTrCH whether fixed or flexible positions are used during the connection. DTX indication bits only indicate when the transmission should be turned off, they are not transmitted.

### 4.2.9.1 Insertion of DTX indication bits with fixed positions

This step of inserting DTX indication bits is used only if the positions of the TrCHs in the radio frame are fixed. With fixed position scheme a fixed number of bits is reserved for each TrCH in the radio frame.

The bits from rate matching are denoted by  $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$ , where  $G_i$  is the number of bits in one TTI of TrCH  $i$ . Denote the number of bits reserved for one radio frame of TrCH  $i$  by  $H_i$ , i.e. the maximum number of bits in a radio frame for any transport format of TrCH  $i$ . The number of radio frames in a TTI of TrCH  $i$  is denoted by  $F_i$ . The bits output from the DTX insertion are denoted by  $h_{i1}, h_{i2}, h_{i3}, \dots, h_{i(F_i H_i)}$ . Note that these bits are three valued. They are defined by the following relations:

$$h_{ik} = g_{ik} \quad k = 1, 2, 3, \dots, G_i$$

$$h_{ik} = \mathbf{d} \quad k = G_i+1, G_i+2, G_i+3, \dots, F_i H_i$$

where DTX indication bits are denoted by  $\mathbf{d}$ . Here  $g_{ik} \in \{0, 1\}$  and  $\mathbf{d} \notin \{0, 1\}$ .

### 4.2.9.2 Insertion of DTX indication bits with flexible positions

Note: Below, it is assumed that all physical channels belonging to the same CCTrCH use the same SF. Hence,  $U_p=U=\text{constant}$ .

This step of inserting DTX indication bits is used only if the positions of the TrCHs in the radio frame are flexible. The DTX indication bits shall be placed at the end of the radio frame. Note that the DTX will be distributed over all slots after 2<sup>nd</sup> interleaving.

The bits input to the DTX insertion block are denoted by  $s_1, s_2, s_3, \dots, s_S$ , where  $S$  is the number of bits from TrCH multiplexing. The number of PhCHs is denoted by  $P$  and the number of bits in one radio frame, including DTX indication bits, for each PhCH by  $U$ .

The bits output from the DTX insertion block are denoted by  $w_1, w_2, w_3, \dots, w_{(PU)}$ . Note that these bits are threevalued. They are defined by the following relations:

$$w_k = s_k \quad k = 1, 2, 3, \dots, S$$

$$w_k = \mathbf{d} \quad k = S+1, S+2, S+3, \dots, PU$$

where DTX indication bits are denoted by  $\mathbf{d}$ . Here  $s_k \in \{0, 1\}$  and  $\mathbf{d} \notin \{0, 1\}$ .

## 4.2.10 Physical channel segmentation

Note: Below, it is assumed that all physical channels belonging to the same CCTrCH use the same SF. Hence,  $U_p=U=\text{constant}$ .

When more than one PhCH is used, physical channel segmentation divides the bits among the different PhCHs. The bits input to the physical channel segmentation are denoted by  $x_1, x_2, x_3, \dots, x_Y$ , where  $Y$  is the number of bits input to the physical channel segmentation block. The number of PhCHs is denoted by  $P$ .

The bits after physical channel segmentation are denoted  $u_{p1}, u_{p2}, u_{p3}, \dots, u_{pU}$ , where  $p$  is PhCH number and  $U$  is

the number of bits in one radio frame for each PhCH, i.e.  $U = \frac{Y}{P}$ . The relation between  $x_k$  and  $u_{pk}$  is given below.

Bits on first PhCH after physical channel segmentation:

$$u_{1k} = x_k \quad k = 1, 2, \dots, U$$

Bits on second PhCH after physical channel segmentation:

$$u_{2k} = x_{(k+U)} \quad k = 1, 2, \dots, U$$

...

Bits on the  $P^{th}$  PhCH after physical channel segmentation:

$$u_{Pk} = x_{(k+(P-1)U)} \quad k = 1, 2, \dots, U$$

#### 4.2.10.1 Relation between input and output of the physical segmentation block in uplink

The bits input to the physical segmentation are denoted by  $s_1, s_2, s_3, \dots, s_S$ . Hence,  $x_k = s_k$  and  $Y = S$ .

#### 4.2.10.2 Relation between input and output of the physical segmentation block in downlink

If fixed positions of the TrCHs in a radio frame are used then the bits input to the physical segmentation are denoted by  $s_1, s_2, s_3, \dots, s_S$ . Hence,  $x_k = s_k$  and  $Y = S$ .

If flexible positions of the TrCHs in a radio frame are used then the bits input to the physical segmentation are denoted by  $w_1, w_2, w_3, \dots, w_{(PU)}$ . Hence,  $x_k = w_k$  and  $Y = PU$ .

### 4.2.11 $2^{nd}$ interleaving

The  $2^{nd}$  interleaving is a block interleaver with inter-column permutations. The bits input to the  $2^{nd}$  interleaver are denoted  $u_{p1}, u_{p2}, u_{p3}, \dots, u_{pU}$ , where  $p$  is PhCH number and  $U$  is the number of bits in one radio frame for one PhCH.

(1) Set the number of columns  $C_2 = 30$ . The columns are numbered 0, 1, 2, ...,  $C_2-1$  from left to right.

(2) Determine the number of rows  $R_2$  by finding minimum integer  $R_2$  such that  $U \leq R_2 C_2$ .

(3) The bits input to the  $2^{nd}$  interleaving are written into the  $R_2 \times C_2$  rectangular matrix row by row.

$$\begin{bmatrix} u_{p1} & u_{p2} & u_{p3} & \dots & u_{p30} \\ u_{p31} & u_{p32} & u_{p33} & \dots & u_{p60} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ u_{p,((R_2-1)30+1)} & u_{p,((R_2-1)30+2)} & u_{p,((R_2-1)30+3)} & \dots & u_{p,(R_2 30)} \end{bmatrix}$$

(4) Perform the inter-column permutation based on the pattern  $\{P_2(j)\}$  ( $j = 0, 1, \dots, C_2-1$ ) that is shown in Table 6, where  $P_2(j)$  is the original column position of the  $j$ -th permuted column. After permutation of the columns, the bits are denoted by  $y_{pk}$ .

$$\begin{bmatrix} y_{p1} & y_{p,(R_2+1)} & y_{p,(2R_2+1)} & \dots & y_{p,(29R_2+1)} \\ y_{p2} & y_{p,(R_2+2)} & y_{p,(2R_2+2)} & \dots & y_{p,(29R_2+2)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ y_{pR_2} & y_{p,(2R_2)} & y_{p,(3R_2)} & \dots & y_{p,(30R_2)} \end{bmatrix}$$

(5) The output of the  $2^{nd}$  interleaving is the bit sequence read out column by column from the inter-column permuted  $R_2 \times C_2$  matrix. The output is pruned by deleting bits that were not present in the input bit sequence, i.e. bits  $y_{pk}$  that corresponds to bits  $u_{pk}$  with  $k > U$  are removed from the output. The bits after  $2^{nd}$  interleaving are denoted by

$v_{p1}, v_{p2}, \dots, v_{pU}$ , where  $v_{p1}$  corresponds to the bit  $y_{pk}$  with smallest index  $k$  after pruning,  $v_{p2}$  to the bit  $y_{pk}$  with second smallest index  $k$  after pruning, and so on.

Table 6

Number of column $C_2$	Inter-column permutation pattern
30	{0, 20, 10, 5, 15, 25, 3, 13, 23, 8, 18, 28, 1, 11, 21, 6, 16, 26, 4, 14, 24, 19, 9, 29, 12, 2, 7, 22, 27, 17}

## 4.2.12 Physical channel mapping

The PhCH for both uplink and downlink is defined in [2]. The bits input to the physical channel mapping are denoted by  $v_{p1}, v_{p2}, \dots, v_{pU}$ , where  $p$  is the PhCH number and  $U$  is the number of bits in one radio frame for one PhCH. The bits  $v_{pk}$  are mapped to the PhCHs so that the bits for each PhCH are transmitted over the air in ascending order with respect to  $k$ .

In compressed mode, no bits are mapped to certain slots of the PhCH(s). If  $N_{first} + TGL \leq 15$ , no bits are mapped to slots  $N_{first}$  to  $N_{last}$ . If  $N_{first} + TGL > 15$ , i.e. the transmission gap spans two consecutive radio frames, the mapping is as follows:

- In the first radio frame, no bits are mapped to slots  $N_{first}, N_{first}+1, N_{first}+2, \dots, 14$ .
- In the second radio frame, no bits are mapped to the slots 0, 1, 2, ...,  $N_{last}$ .

$TGL$ ,  $N_{first}$ , and  $N_{last}$  are defined in Section 4.4.

### 4.2.12.1 Uplink

In uplink, the PhCHs used during a radio frame are either completely filled with bits that are transmitted over the air or not used at all. The only exception is when the UE is in compressed mode. The transmission can then be turned off during consecutive slots of the radio frame.

### 4.2.12.2 Downlink

In downlink, the PhCHs do not need to be completely filled with bits that are transmitted over the air. Bits  $v_{pk} \notin \{0, 1\}$  are not transmitted.

The following rules should be used for the selection of fixed or flexible positions of the TrCHs in the radio frame:

- For TrCHs not relying on TFCI for transport format detection (blind transport format detection), the positions of the transport channels within the radio frame should be fixed. In a limited number of cases, where there are a small number of transport format combinations, it is possible to allow flexible positions.
- For TrCHs relying on TFCI for transport format detection, higher layer signal whether the positions of the transport channels should be fixed or flexible.

## 4.2.13 Restrictions on different types of CCTrCHs

Restrictions on the different types of CCTrCHs are described in general terms in TS 25.302[11]. In this section those restrictions are given with layer 1 notation.

### 4.2.13.1 Uplink Dedicated channel (DCH)

The maximum value of the number of TrCHs  $I$  in a CCTrCH, the maximum value of the number of transport blocks  $M_i$  on each transport channel, and the maximum value of the number of DPDCHs  $P$  are given from the UE capability class.

#### 4.2.13.2 Random Access Channel (RACH)

- There can only be one TrCH in each RACH CCTrCH, i.e.  $I=1$ ,  $s_k = f_{1k}$  and  $S = V_1$ .
- The maximum value of the number of transport blocks  $M_1$  on the transport channel is given from the UE capability class.
- The transmission time interval is always 10 ms, i.e.  $e_{1k} = c_{1k}$  and  $N_1 = E_1$ .
- At initial RACH transmission the rate matching attribute has a predefined value.
- Only one PRACH is used, i.e.  $P=1$ ,  $u_{1k} = s_k$ , and  $U = S$ .

#### 4.2.13.3 Common Packet Channel (CPCH)

- The maximum value of the number of TrCHs  $I$  in a CCTrCH, the maximum value of the number of transport blocks  $M_i$  on each transport channel, and the maximum value of the number of DPDCHs  $P$  are given from the UE capability class.

Note: Only the data part of the CPCH can be mapped on multiple physical channels (this note is taken from TS 25.302).

#### 4.2.13.4 Downlink Dedicated Channel (DCH)

The maximum value of the number of TrCHs  $I$  in a CCTrCH, the maximum value of the number of transport blocks  $M_i$  on each transport channel, and the maximum value of the number of DPDCHs  $P$  are given from the UE capability class.

#### 4.2.13.5 Downlink Shared Channel (DSCH) associated with a DCH

- The spreading factor is indicated with the TFCI or with higher layer signalling on DCH.
- There can only be one TrCH in each DSCH CCTrCH, i.e.  $I=1$ ,  $s_k = f_{1k}$  and  $S = V_1$ .
- The maximum value of the number of transport blocks  $M_1$  on the transport channel and the maximum value of the number of PDSCHs  $P$  are given from the UE capability class.

#### 4.2.13.6 Broadcast channel (BCH)

- There can only be one TrCH in the BCH CCTrCH, i.e.  $I=1$ ,  $s_k = f_{1k}$ , and  $S = V_1$ .
- There can only be one transport block in each transmission time interval, i.e.  $M_1 = 1$ .
- All transport format attributes have predefined values.
- Only one primary CCPCH is used, i.e.  $P=1$ .

#### 4.2.13.7 Forward access and paging channels (FACH and PCH)

- The maximum value of the number of TrCHs  $I$  in a CCTrCH and the maximum value of the number of transport blocks  $M_i$  on each transport channel are given from the UE capability class.
- The transmission time interval for TrCHs of PCH type is always 10 ms.
- Only one secondary CCPCH is used per CCTrCH, i.e.  $P=1$ .

### 4.2.14 Multiplexing of different transport channels into one CCTrCH, and mapping of one CCTrCH onto physical channels

The following rules shall apply to the different transport channels which are part of the same CCTrCH:

- 1) Transport channels multiplexed into one CCTrCH should have co-ordinated timings in the sense that transport blocks arriving from higher layers on different transport channels of potentially different transmission time intervals shall have aligned transmission time instants as shown in Figure 8.

**Figure 8: Possible transmission time instants regarding CCTrCH**

- 2) Only transport channels with the same active set can be mapped onto the same CCTrCH.
- 3) Different CCTrCHs cannot be mapped onto the same PhCH.
- 4) One CCTrCH shall be mapped onto one or several PhCHs. These physical channels shall all have the same SF.
- 5) Dedicated Transport channels and common transport channels cannot be multiplexed into the same CCTrCH
- 6) For the common transport channels, only the FACH and PCH may belong to the same CCTrCH

There are hence two types of CCTrCH

- 1) CCTrCH of dedicated type, corresponding to the result of coding and multiplexing of one or several DCHs.
- 2) CCTrCH of common type, corresponding to the result of the coding and multiplexing of a common channel, RACH in the uplink, DSCH ,BCH, or FACH/PCH for the downlink.

#### 4.2.14.1 Allowed CCTrCH combinations for one UE

##### 4.2.14.1.1 Allowed CCTrCH combinations on the uplink

A maximum of one CCTrCH is allowed for one UE on the uplink. It can be either

- 1) one CCTrCH of dedicated type
- 2) one CCTrCH of common type

##### 4.2.14.1.2 Allowed CCTrCH combinations on the downlink

The following CCTrCH combinations for one UE are allowed :

x CCTrCH of dedicated type + y CCTrCH of common type

The allowed combination of CCTrCHs of dedicated and common type are FFS.

Note 1 : There is only one DPCCCH in the uplink, hence one TPC bits flow on the uplink to control possibly the different DPDCHs on the downlink, part of the same or several CCTrCHs.

Note 2 : There is only one DPCCCH in the downlink, even with multiple CCTrCHs. With multiple CCTrCHs, the DPCCCH is transmitted on one of the physical channels of that CCTrCH which has the smallest SF among the multiple CCTrCHs. Thus there is only one TPC command flow and only one TFCI word in downlink even with multiple CCTrCHs.

#### 4.2.15 System Frame Number (SFN)

- SFN indicates super frame synchronisation. It is broadcasted in BCH. (See TS 25.211[2])  
<Editor’s note: Length of SFN is FFS. It will be determined according to requirement from WG2 and WG3>
- SFN is multiplexed with a BCH transport block (see Figure 9).
- SFN is applied CRC calculation and FEC with BCH transport block.

Figure 9: SFN multiplexing

### 4.3 Transport format detection

Transport format detection can be performed both with and without Transport Format Combination Indicator (TFCI). If a TFCI is transmitted, the receiver detects the transport format combination from the TFCI. When no TFCI is transmitted, so called blind transport format detection is used, i.e. the receiver side detects the transport format combination using some information, e.g. received power ratio of DPDCH to DPCCH, CRC check results.

For uplink, the blind transport format detection is an operator option. For downlink, the blind transport format detection can be applied with convolutional coding, the maximum number of different transport formats and maximum data rates allowed shall be specified.

#### 4.3.1 Blind transport format detection

Examples of blind transport format detection methods are given in Annex A.

#### 4.3.2 Explicit transport format detection based on TFCI

The Transport Format Combination Indicator (TFCI) informs the receiver of the transport format combination of the CCTrCHs. As soon as the TFCI is detected, the transport format combination, and hence the individual transport channels' transport formats are known, and decoding of the transport channels can be performed.

#### 4.3.3 Coding of Transport-format-combination indicator (TFCI)

The number of TFCI bits is variable and is set at the beginning of the call via higher layer signalling. For improved TFCI detection reliability, in downlink, repetition is used by increasing the number of TFCI bits within a slot.

The TFCI bits are encoded using (30, 10) punctured sub-code of the second order Reed-Muller code. The coding procedure is as shown in Figure 10.

Figure 10: Channel coding of TFCI bits

If the TFCI consist of less than 10 bits, it is padded with zeros to 10 bits, by setting the most significant bits to zero. The receiver can use the information that not all 10 bits are used for the TFCI, thereby reducing the error rate in the TFCI decoder. The length of the TFCI code word is 30 bits. Thus there are 2 bits of (encoded) TFCI in every slot of the radio frame.

Firstly, TFCI is encoded by the (32,10) sub-code of second order Reed-Muller code. The code words of the (32,10) sub-code of second order Reed-Muller code are linear combination of 10 basis sequences: all 1's, 5 OVSF codes ( $C_{32,1}$ ,  $C_{32,2}$ ,  $C_{32,4}$ ,  $C_{32,8}$ ,  $C_{32,16}$ ), and 4 masks (Mask1, Mask2, Mask3, Mask4). The 4 mask sequences are as following Table 7.

Table 7: Mask sequences

Mask 1	00101000011000111111000001110111
Mask 2	00000001110011010110110111000111
Mask 3	00001010111110010001101100101011
Mask 4	00011100001101110010111101010001

For information bits  $a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9$  ( $a_0$  is LSB and  $a_9$  is MSB), the encoder structure is as following Figure 11.

Figure 11: Encoder structure for (32,10) sub-code of second order Reed-Muller code

Then, the code words of the (32,10) sub-code of second order Reed-Muller code are punctured into length 30 by puncturing 1st and 17th bits. The remaining bits are denoted by  $b_k, k = 0, 1, 2, \dots, 29$  ( $k = 29$  corresponds to the MSB bit).

In downlink, when the SF is lower than 128 the encoded and punctured TFCI code words are repeated four times yielding 8 encoded TFCI bits per slot. Mapping of repeated bits to slots is explained in section 4.3.5.

### 4.3.4 Operation of Transport-format-combination indicator (TFCI) in Split Mode

In the case of DCH in Split Mode, the UTRAN shall operate with as follows:

- If one of the links is associated with a DSCH, the TFCI code word may be split in such a way that the code word relevant for TFCI activity indication is not transmitted from every cell. The use of such a functionality shall be indicated by higher layer signalling.

TFCI information is encoded by biorthogonal (16, 5) block code. The code words of the biorthogonal (16, 5) code are from two mutually biorthogonal sets,  $S_{C_{16}} = \{C_{16,0}, C_{16,1}, \dots, C_{16,15}\}$  and its binary complement,  $\bar{S}_{C_{16}} = \{\bar{C}_{16,0}, \bar{C}_{16,1}, \dots, \bar{C}_{16,15}\}$ . Code words of set  $S_{C_{16}}$  are from the level 16 of the code three of OVSF codes defined in document TS 25.213. The mapping of information bits to code words is shown in the Table 8.

**Table 8: Mapping of information bits to code words for biorthogonal (16, 5) code**

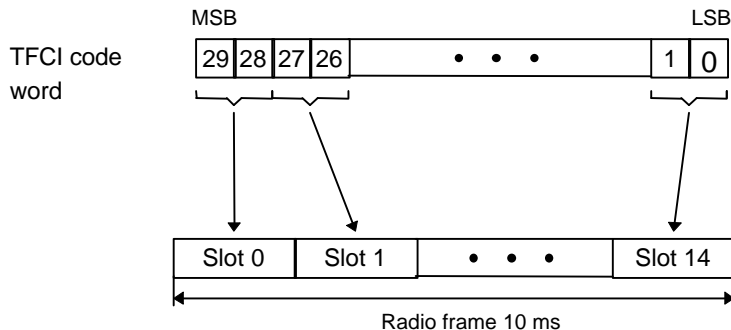

Information bits	Code word
00000	$C_{16,0}$
00001	$\bar{C}_{16,0}$
00010	$C_{16,1}$
...	...
11101	$\bar{C}_{16,14}$
11110	$C_{16,15}$
11111	$\bar{C}_{16,15}$

Biorthogonal code words,  $C_{16,i}$  and  $\bar{C}_{16,i}$ , are then punctured into length 15 by puncturing the 1st bit. The bits in the code words are denoted by  $b_{j,k}$ , where subscript  $j$  indicates the code word and subscript  $k$  indicates bit position in the code word ( $k = 14$  corresponds to the MSB bit).

### 4.3.5 Mapping of TFCI words

#### 4.3.5.1 Mapping of TFCI word

As only one code word for TFCI is needed no channel interleaving for the encoded bits are done. Instead, the bits of the code word are directly mapped to the slots of the radio frame as depicted in the Figure 12. Within a slot the more significant bit is transmitted before the less significant bit.

**Figure 12: Mapping of TFCI code words to the slots of the radio frame**

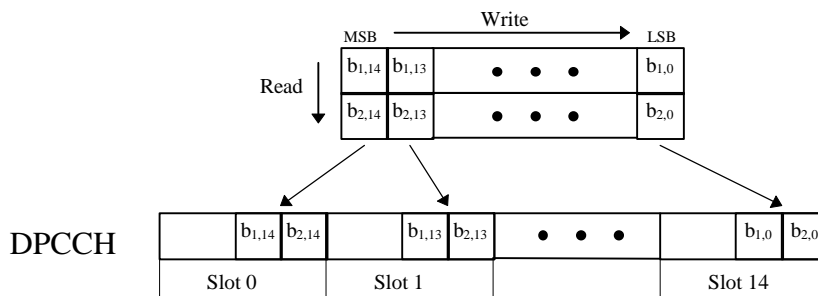

For downlink physical channels whose SF is lower than 128, bits of the TFCI code words are repeated and mapped to slots as shown in the Table 9. Code word bits are denoted as  $b_k^l$ , where subscript  $k$ , indicates bit position in the code word ( $k = 29$  is the MSB bit) and superscript  $l$  indicates bit repetition. In each slot transmission order of the bits is from left to right in the Table 9.

**Table 9: Mapping order of repetition encoded TFCI code word bits into slots.**

Slot	TFCI code word bits							
0	$b_{29}^1$	$b_{29}^2$	$b_{29}^3$	$b_{29}^4$	$b_{28}^1$	$b_{28}^2$	$b_{28}^3$	$b_{28}^4$
1	$b_{27}^1$	$b_{27}^2$	$b_{27}^3$	$b_{27}^4$	$b_{26}^1$	$b_{26}^2$	$b_{26}^3$	$b_{26}^4$
2	$b_{25}^1$	$b_{25}^2$	$b_{25}^3$	$b_{25}^4$	$b_{24}^1$	$b_{24}^2$	$b_{24}^3$	$b_{24}^4$
3	$b_{23}^1$	$b_{23}^2$	$b_{23}^3$	$b_{23}^4$	$b_{22}^1$	$b_{22}^2$	$b_{22}^3$	$b_{22}^4$
4	$b_{21}^1$	$b_{21}^2$	$b_{21}^3$	$b_{21}^4$	$b_{20}^1$	$b_{20}^2$	$b_{20}^3$	$b_{20}^4$
5	$b_{19}^1$	$b_{19}^2$	$b_{19}^3$	$b_{19}^4$	$b_{18}^1$	$b_{18}^2$	$b_{18}^3$	$b_{18}^4$
6	$b_{17}^1$	$b_{17}^2$	$b_{17}^3$	$b_{17}^4$	$b_{16}^1$	$b_{16}^2$	$b_{16}^3$	$b_{16}^4$
7	$b_{15}^1$	$b_{15}^2$	$b_{15}^3$	$b_{15}^4$	$b_{14}^1$	$b_{14}^2$	$b_{14}^3$	$b_{14}^4$
8	$b_{13}^1$	$b_{13}^2$	$b_{13}^3$	$b_{13}^4$	$b_{12}^1$	$b_{12}^2$	$b_{12}^3$	$b_{12}^4$
9	$b_{11}^1$	$b_{11}^2$	$b_{11}^3$	$b_{11}^4$	$b_{10}^1$	$b_{10}^2$	$b_{10}^3$	$b_{10}^4$
10	$b_9^1$	$b_9^2$	$b_9^3$	$b_9^4$	$b_8^1$	$b_8^2$	$b_8^3$	$b_8^4$
11	$b_7^1$	$b_7^2$	$b_7^3$	$b_7^4$	$b_6^1$	$b_6^2$	$b_6^3$	$b_6^4$
12	$b_5^1$	$b_5^2$	$b_5^3$	$b_5^4$	$b_4^1$	$b_4^2$	$b_4^3$	$b_4^4$
13	$b_3^1$	$b_3^2$	$b_3^3$	$b_3^4$	$b_2^1$	$b_2^2$	$b_2^3$	$b_2^4$
14	$b_1^1$	$b_1^2$	$b_1^3$	$b_1^4$	$b_0^1$	$b_0^2$	$b_0^3$	$b_0^4$

4.3.5.2 Mapping of TFCI word in Split Mode

After channel encoding of the two 5 bit TFCI words there are two code words of length 15 bits. They are mapped to DPCCH as shown in the Figure 13. Note that  $b_{1,k}$  and  $b_{2,k}$  denote the bit  $k$  of code word 1 and code word 2, respectively.

**Figure 13: Mapping of TFCI code words to the slots of the radio frame in Split Mode**

For downlink physical channels whose SF is lower than 128, bits of the extended TFCI code words are repeated and mapped to slots as shown in the Table 10. Code word bits are denoted as  $b_{j,k}^l$ , where subscript  $j$  indicates the code word, subscript  $k$  indicates bit position in the code word ( $k=14$  is the MSB bit) and superscript  $l$  indicates bit repetition. In each slot transmission order of the bits is from left to right in the Table 10.

**Table 10: Mapping order of repetition encoded TFCI code word bits to slots in Split Mode**

Slot	TFCI code word bits in split mode							
0	$b_{1,14}^1$	$b_{1,14}^2$	$b_{1,14}^3$	$b_{1,14}^4$	$b_{2,14}^1$	$b_{2,14}^2$	$b_{2,14}^3$	$b_{2,14}^4$
1	$b_{1,13}^1$	$b_{1,13}^2$	$b_{1,13}^3$	$b_{1,13}^4$	$b_{2,13}^1$	$b_{2,13}^2$	$b_{2,13}^3$	$b_{2,13}^4$
2	$b_{1,12}^1$	$b_{1,12}^2$	$b_{1,12}^3$	$b_{1,12}^4$	$b_{2,12}^1$	$b_{2,12}^2$	$b_{2,12}^3$	$b_{2,12}^4$
3	$b_{1,11}^1$	$b_{1,11}^2$	$b_{1,11}^3$	$b_{1,11}^4$	$b_{2,11}^1$	$b_{2,11}^2$	$b_{2,11}^3$	$b_{2,11}^4$
4	$b_{1,10}^1$	$b_{1,10}^2$	$b_{1,10}^3$	$b_{1,10}^4$	$b_{2,10}^1$	$b_{2,10}^2$	$b_{2,10}^3$	$b_{2,10}^4$
5	$b_{1,9}^1$	$b_{1,9}^2$	$b_{1,9}^3$	$b_{1,9}^4$	$b_{2,9}^1$	$b_{2,9}^2$	$b_{2,9}^3$	$b_{2,9}^4$
6	$b_{1,8}^1$	$b_{1,8}^2$	$b_{1,8}^3$	$b_{1,8}^4$	$b_{2,8}^1$	$b_{2,8}^2$	$b_{2,8}^3$	$b_{2,8}^4$
7	$b_{1,7}^1$	$b_{1,7}^2$	$b_{1,7}^3$	$b_{1,7}^4$	$b_{2,7}^1$	$b_{2,7}^2$	$b_{2,7}^3$	$b_{2,7}^4$
8	$b_{1,6}^1$	$b_{1,6}^2$	$b_{1,6}^3$	$b_{1,6}^4$	$b_{2,6}^1$	$b_{2,6}^2$	$b_{2,6}^3$	$b_{2,6}^4$
9	$b_{1,5}^1$	$b_{1,5}^2$	$b_{1,5}^3$	$b_{1,5}^4$	$b_{2,5}^1$	$b_{2,5}^2$	$b_{2,5}^3$	$b_{2,5}^4$
10	$b_{1,4}^1$	$b_{1,4}^2$	$b_{1,4}^3$	$b_{1,4}^4$	$b_{2,4}^1$	$b_{2,4}^2$	$b_{2,4}^3$	$b_{2,4}^4$
11	$b_{1,3}^1$	$b_{1,3}^2$	$b_{1,3}^3$	$b_{1,3}^4$	$b_{2,3}^1$	$b_{2,3}^2$	$b_{2,3}^3$	$b_{2,3}^4$
12	$b_{1,2}^1$	$b_{1,2}^2$	$b_{1,2}^3$	$b_{1,2}^4$	$b_{2,2}^1$	$b_{2,2}^2$	$b_{2,2}^3$	$b_{2,2}^4$
13	$b_{1,1}^1$	$b_{1,1}^2$	$b_{1,1}^3$	$b_{1,1}^4$	$b_{2,1}^1$	$b_{2,1}^2$	$b_{2,1}^3$	$b_{2,1}^4$
14	$b_{1,0}^1$	$b_{1,0}^2$	$b_{1,0}^3$	$b_{1,0}^4$	$b_{2,0}^1$	$b_{2,0}^2$	$b_{2,0}^3$	$b_{2,0}^4$

### 4.3.5.3 Mapping of TFCI in compressed mode

The mapping of the TFCI bits in compressed mode is dependent on the transmission time reduction method. Denote the TFCI bits by  $c_0, c_1, c_2, c_3, c_4, \dots, c_C$ , where:

- $c_k = b_k$ ,  $C = 29$ , when there are 2 TFCI bit in each slot.
- $c_0 = b_0^4, c_1 = b_0^3, c_2 = b_0^2, c_3 = b_0^1, c_4 = b_1^4, c_5 = b_1^3, \dots, c_{119} = b_{14}^1$ , when there are 8 TFCI bits in each slot.
- $c_0 = b_{2,0}, c_1 = b_{1,0}, c_3 = b_{2,1}, c_4 = b_{1,1}, \dots, c_{29} = b_{1,14}$ , in split mode when there are 2 TFCI bits in each slot.
- $c_0 = b_{2,0}^4, c_1 = b_{2,0}^3, c_2 = b_{2,0}^2, c_3 = b_{2,0}^1, c_4 = b_{1,0}^4, c_5 = b_{1,0}^3, \dots, c_{119} = b_{1,14}^1$ , in split mode when there are 8 TFCI bits in each slot.

The TFCI mapping for each transmission method is given in the sections below.

#### 4.3.5.3.1 Compressed mode method A

For compressed mode by method A, all the TFCI bits are mapped to the remaining slots. The number of bits per slot in uncompressed mode is denoted by  $Z$  and  $Z = (C + 1)/15$ . The mapping to slots for different TGLs are defined below.

##### 4.3.5.3.1.1 TGL of 3 slots

Slot number  $3 + 2x$  contain bits  $c_{C-\frac{5}{2}Zx}, c_{C-\frac{5}{2}Zx-1}, \dots, c_{C-\frac{5}{2}Zx-\frac{3}{2}Z-1}$ , where  $x = 0, 1, 2, 3, 4, 5$

Slot number  $4 + 2x$  contain bits  $c_{C-\frac{3}{2}Z-\frac{5}{2}Zx}, c_{C-\frac{3}{2}Z-\frac{5}{2}Zx-1}, \dots, c_{C-\frac{3}{2}Z-\frac{5}{2}Zx-(Z-1)}$ , where  $x = 0, 1, 2, 3, 4, 5$

The case when  $C = 29$  is illustrated in Figure 14.

Figure 14: Mapping of TFCI code with TGL of 3 slots.

4.3.5.3.1.2 TGL of 4 slots

Slot number 4 does not contain any TFCI bits.

Slot number 5 + x contain bits  $c_{C-\frac{3}{2}Zx}$ ,  $c_{C-\frac{3}{2}Z(x-1)}$ , ...,  $c_{C-\frac{3}{2}Z(x-\frac{3}{2}Z-1)}$ , where  $x = 0, 1, 2, 3, \dots, 9$

The case when  $C = 29$  is illustrated in Figure 15.

Figure 15: Mapping of TFCI code with TGL of 4 slots.

4.3.5.3.2 Compressed mode method B

4.3.5.3.2.1 Uplink

For uplink compressed mode by method B the frame format is changed so that no TFCI bits are lost. The different frame formats in compressed mode can not match the exact number of TFCI bits for all possible TGLs. Repetition of the TFCI bits is therefore used.

Denote the number of bits available in the TFCI fields of one compressed radio frame by  $D$ , the repeated bits by  $d_k$ , and the number of bits in the TFCI field in a slot by  $N_{TFCI}$ . Let  $E=30-1-(N_{first}N_{TFCI})\text{mod } 30$ . If  $N_{last} \neq 14$ , then  $E$  corresponds to the number of the first TFCI bit in the slot directly after the TG. The following relations then define the repetition.

$$d_{D-31} = c_{E \text{ mod } 30}, d_{D-32} = c_{(E-1) \text{ mod } 30}, d_{D-33} = c_{(E-2) \text{ mod } 30}, \dots, d_0 = c_{(E-(D-31)) \text{ mod } 30}$$

The bits are mapped to the slots in descending order starting with the original bits and followed by the repeated ones, i.e.  $c_{29}$  is sent as first bit in the TFCI field of the first transmitted slot and  $d_0$  as last bit in the TFCI field of the last transmitted slot.

4.3.5.3.2.2 Downlink

<Editor's note: Detailed description for downlink is FFS>

### 4.4 Compressed mode

In compressed mode, slots  $N_{\text{first}}$  to  $N_{\text{last}}$  are not used for transmission of data. As illustrated in Figure 16, which shows the example of fixed transmission gap position with single frame method, the instantaneous transmit power is increased in the compressed frame in order to keep the quality (BER, FER, etc.) unaffected by the reduced processing gain. The amount of power increase depends on the transmission time reduction method (see section 4.4.3). What frames are compressed, are decided by the network. When in compressed mode, compressed frames can occur periodically, as illustrated in Figure 16, or requested on demand. The rate and type of compressed frames is variable and depends on the environment and the measurement requirements.

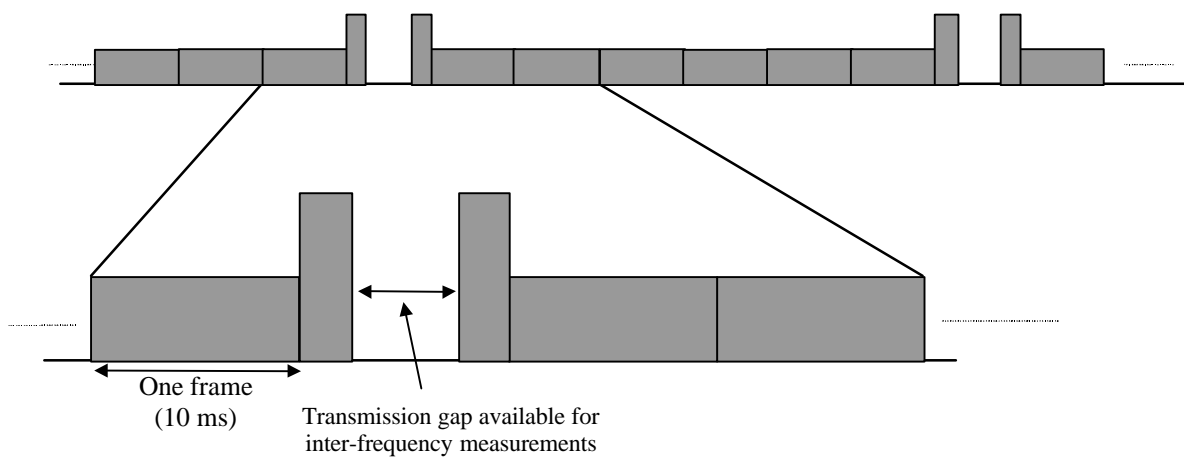

Figure 16: Compressed mode transmission

#### 4.4.1 Frame structure in the uplink

The frame structure for uplink compressed mode is illustrated in Figure 17.

Figure 17: Frame structure in uplink compressed transmission

#### 4.4.2 Frame structure types in the downlink

There are two different types of frame structures defined for downlink compressed transmission. Type A is the basic case, which maximises the transmission gap length. Type B, which is more optimised for power control, can be used if the requirement of the transmission gap length allows that.

- With frame structure of type A, BTS transmission is off from the beginning of TFCI field in slot  $N_{first}$ , until the end of Data2 field in slot  $N_{last}$  (Figure 18(a)).
- With frame structure of type B, BTS transmission is off from the beginning of Data2 field in slot  $N_{first}$ , until the end of Data2 field in slot  $N_{last}$  (Figure 18(b)) Dummy bits are transmitted in the TFCI and Data1 fields of slot  $N_{first}$ , and BTS and MS do not use the dummy bits. Thus BTS and MS utilize only the TPC field of  $N_{first}$ .

(a) Frame structure type A

(b) Frame structure type B

**Figure 18: Frame structure types in downlink compressed transmission**

### 4.4.3 Transmission time reduction method

When in compressed mode, the information normally transmitted during a 10 ms frame is compressed in time. The mechanism provided for achieving this is either changing the code rate (method A), which means puncturing in practice, or the reduction of the spreading factor by a factor of two (method B). In the downlink, both method A and B are supported while only method B is used in the uplink. The maximum idle length is defined to be 7 slots per one 10 ms frame.

#### 4.4.2.1 Method A: By puncturing

During compressed mode, rate matching (puncturing) is applied for creating transmission gap in one frame. The algorithm for rate matching (puncturing) as described in Section 4.2.7 is used.

DPDCH and DPCCH fields for compressed mode when puncturing 4 slots and 3 slots, respectively, are shown in Table 11 and Table 12. Because of higher encoding rate, some DPDCH symbols remain unused and shall be indicated as DTX.

**Table 11: DPDCH and DPCCH fields in compressed mode when puncturing 4 slots**

Channel Bit Rate (kbps)	Channel Symbol Rate (ksps)	SF	Bits/Frame			Bits/Slot	DPDCH Bits/Slot		DPCCH Bits/Slot			Extra DPDCH symbols for DTX

- 1) This figure does not take into account the extra TFCI bits from deleted slots
- 2) If TFCI bits are not used, then DTX shall be used in TFCI field

Note: Compressed mode with puncturing cannot be used for SF=512 with TFCI

#### 4.4.3.2 Method B: By reducing the spreading factor by 2

During compressed mode, the spreading factor (SF) can be reduced by 2 to enable the transmission of the information bits in the remaining time slots of a compressed frame.

On the downlink, UTRAN can also order the UE to use a different scrambling code in compressed mode than in normal mode. If the UE is ordered to use a different scrambling code in compressed mode, then there is a one-to-one mapping between the scrambling code used in normal mode and the one used in compressed mode, as described in TS 25.213[3] section 5.2.1.

The uplink DPCCH fields in compressed mode are defined in Table 13.

<Editor's note: Downlink fields structure is FFS.>

**Table 13: Uplink DPCCH fields in compressed mode**

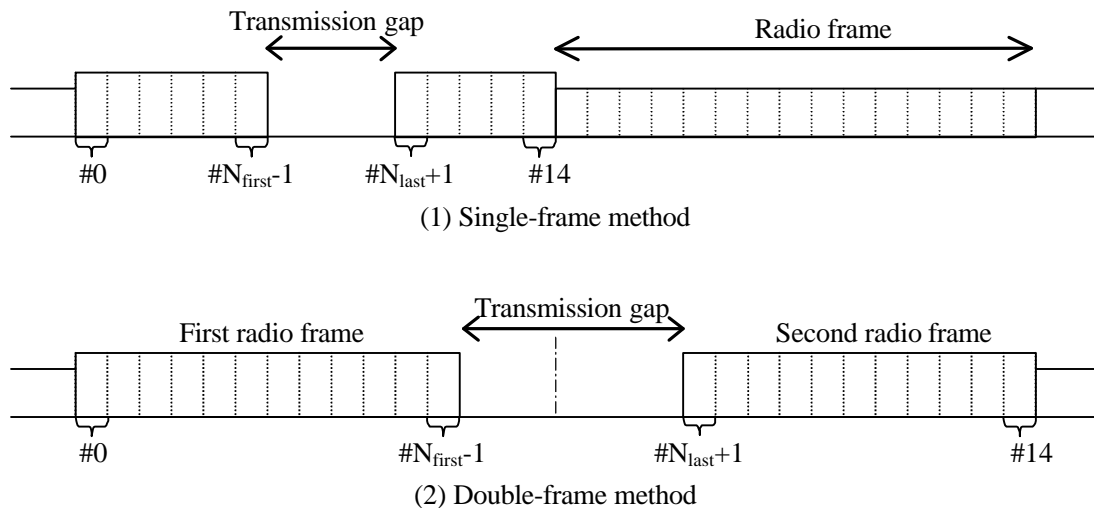

Format number	Channel Bit Rate (kbps)	Channel Symbol Rate (ksps)	SF	Bits/ Frame	Bits/ Slot	$N_{\text{pilot}}$	$N_{\text{TPC}}$	$N_{\text{TFCI}}$	$N_{\text{FBI}}$	Transmitted slots per radio frame
0	15	15	256	150	10	6	2	2	0	15
0A	15	15	256	150	10	5	2	3	0	10-14
0B	15	15	256	150	10	4	2	4	0	8-9
1	15	15	256	150	10	8	2	0	0	8-15
2	15	15	256	150	10	5	2	2	1	15
2A	15	15	256	150	10	4	2	3	1	10-14

5A	15	15	256	150	10	4	1	3	2	10-14
5B	15	15	256	150	10	3	1	4	2	8-9

#### 4.4.4 Transmission gap position

Transmission gaps can be placed at both fixed position and adjustable position for each purpose such as interfrequency power measurement, acquisition of control channel of other system/carrier, and actual handover operation.

##### 4.4.3.1 Fixed transmission gap position

The transmission gaps can be placed onto fixed positions. When using single frame method, the fixed transmission gap is located within the compressed frame depending on the transmission gap length (TGL) as shown in Figure 19 (1). When using double frame method, the fixed transmission gap is located on the center of two connected frames as shown in Figure 19 (2). Table 14 shows the parameters for the fixed transmission gap position case.

**Figure 19: Fixed transmission gap position**

**Table 14: Parameters for fixed transmission gap position**

TGL (slot)	Single-frame method		Double-frame method	
	$N_{\text{first}}$	$N_{\text{last}}$	$N_{\text{first}}$	$N_{\text{last}}$
3	7	9	14 in first frame	1 in second frame
4	6	9	13 in first frame	1 in second frame
7	6	12	12 in first frame	3 in second frame
10	N.A.	N.A.	10 in first frame	4 in second frame
14	N.A.	N.A.	8 in first frame	6 in second frame

#### 4.4.4.2 Adjustable transmission gap position

Position of transmission gaps can be adjustable/relocatable for some purpose e.g. data acquisition on certain position as shown in Figure 20. Parameters of the adjustable transmission gap positions are calculated as follows:

TGL is the number of consecutive idle slots during compressed mode,

$$\text{TGL} = 3, 4, 7, 10, 14$$

$N_{\text{first}}$  specifies the starting slot of the consecutive idle slots,

$$N_{\text{first}} = 0, 1, 2, 3, \dots, 14.$$

$N_{\text{last}}$  shows the number of the final idle slot and is calculated as follows;

$$\text{If } N_{\text{first}} + \text{TGL} \leq 15, \text{ then } N_{\text{last}} = N_{\text{first}} + \text{TGL} - 1 \text{ ( in the same frame )},$$

$$\text{If } N_{\text{first}} + \text{TGL} > 15, \text{ then } N_{\text{last}} = (N_{\text{first}} + \text{TGL} - 1) \bmod 15 \text{ ( in the next frame )}.$$

When the transmission gap spans two consecutive radio frames,  $N_{\text{first}}$  and TGL must be chosen so that at least 8 slots in each radio frame are transmitted.

Figure 20: Adjustable transmission gap lengths position

4.4.4.3 Parameters for downlink compressed mode

< Editor's note: WG1 suggestion is that there is need for further clarifications in Table 15 (e.g. rationales between change of coding rate/puncturing/change of spreading factor and idle time size, spreading factor range for different modes, etc.).>

Table 15 shows the detailed parameters for each transmission gap length when transmission time reduction methods A or B are used.

**Table 15: Parameters for compressed mode**

TGL	Type	Adjustable /fixed gap position	Spreading Factor	Idle length[ms]	Transmission time Reduction method	Idle frame Combining	
3	A	Adjustable	512 - 4	1.73-1.99	Puncturing	(S) (D) =(1,2),(2,1)	
	B		256- 4	1.60-1.86			
4	A	Or Fixed	512 - 4	2.40-2.66	Spreading factor reduction by 2	(S) (D) =(1,3),(2,2),(3,1)	
	B		256- 4	2.27-2.53			
7	A		512 -4	4.40-4.66		(S) (D)=(1,6),(2,5),(3,4),(4,3),(5,2),(6,1)	
	B		256- 4	4.27-4.53			
10	A		512 - 4	6.40-6.66		(D)=(3,7),(4,6),(5,5),(6,4),(7,3)	
	B		256- 4	6.27-6.53			
14	A		Fixed	512 - 4		9.07-9.33	(D) =(7,7)
	B			256- 4		8.93-9.19	

(S): Single-frame method as shown in Figure 19 (1).

(D): Double-frame method as shown in Figure 19 (2). (x,y) indicates x: the number of idle slots in the first frame, y: the number of idle slots in the second frame.

Note: Details for the use of the spreading factor reduction method with SF=4 are FFS

## Annex A (informative): Blind transport format detection

### A.1 Blind transport format detection using fixed positions

#### A.1.1 Blind transport format detection using received power ratio

- This method is used for dual transport format case (the possible data rates, 0 and full rate, and only transmitting CRC for full rate).
- The rate detection is done using average received power ratio of DPDCH to DPCCH.
  - P<sub>c</sub>*: Received Power per bit of DPCCH calculated from all pilot and TPC bits per slot over 10ms frame.
  - P<sub>d</sub>*: Received Power per bit of DPDCH calculated from *X* bits per slot over 10ms frame.
  - X*: the number of DPDCH bits per slot when transport format corresponds to full rate.
  - T*: Threshold of average received power ratio of DPDCH to DPCCH for rate detection.

If  $P_d/P_c > T$  then

“TX\_ON”

else

“TX\_OFF”

#### A.1.2 Blind transport format detection using CRC

- This method is used for multiple transport format case (the possible data rates: 0, ..., (full rate)/*r*, ..., full rate, and always transmitting CRC for all transport formats).
- At the transmitter, the variable-rate DCH data to be transmitted is block-encoded using a cyclic redundancy check (CRC) and then convolutionally encoded. It is necessary that the CRC parity bits are mapped on the head position (or certain position) in a frame as shown in Figure A-1.
- The receiver knows only the possible transport formats (or the possible end bit position {*n<sub>end</sub>*} by Layer-3 negotiation (See Figure A-1). The receiver performs Viterbi-decoding on the soft decision sample sequence. The correct trellis path of the Viterbi-decoder ends at the zero state at the correct end bit position.
- Blind rate detection method by using CRC traces back the surviving trellis path ending at the zero state (hypothetical trellis path) at each possible end bit position to recover the data sequence. Each recovered data sequence is then error-detected by CRC and if there is no error, the recovered sequence is declared to be correct.
- The following variable is defined:

$$s(n_{\text{end}}) = -10 \log \left( \frac{a_0(n_{\text{end}}) - a_{\min}(n_{\text{end}})}{a_{\max}(n_{\text{end}}) - a_{\min}(n_{\text{end}})} \right) \text{ [dB]} \quad (\text{Eq. 1})$$

where  $a_{\max}(n_{\text{end}})$  and  $a_{\min}(n_{\text{end}})$  are, respectively, the maximum and minimum path-metric valuse among all survivors at end bit position  $n_{\text{end}}$ , and  $a_0(n_{\text{end}})$  is the path-metric value at zero state.

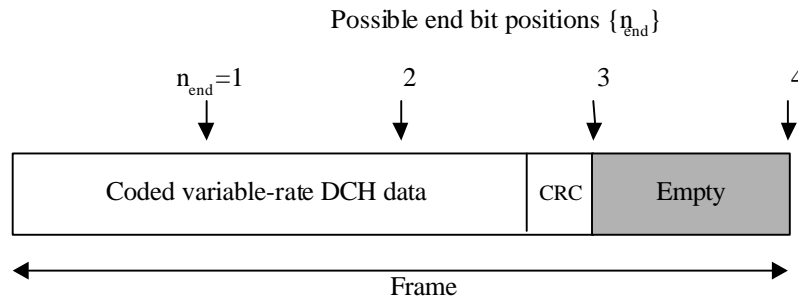

- In order to reduce the probability of false detection (this happens if the selected path is wrong but the CRC misses the error detection), a path selection threshold *D* is introduced. *D* determines whether the hypothetical trellis path connected to the zero state should be traced back or not at each end bit position  $n_{\text{end}}$ . If the hypothetical trellis path connected to the zero state that satisfies

$$s(n_{\text{end}}) \leq D \quad (\text{Eq. 2})$$

is found, the path is traced back to recover the frame data, where *D* is the path selection threshold and a design parameter.

- If more than one end bit positions satisfying Eq. 2 are found, the end bit position which has minimum value of  $s(n_{\text{end}})$  is declared to be correct.
- If no path satisfying Eq. 2 is found even after all possible end bit positions have been exhausted, the received frame data is declared to be in error.

Figure A-2 shows the procedure of blind transport format detection using CRC.

**Figure A-1: An example of variable rate data format**  
 (Number of possible transport formats = 4, transmitted end bit position  $n_{end} = 3$ )

## A.2 Blind transport format detection with flexible positions

In certain cases where the CTrCH consists of multiple transport channels and a small number of transport format combinations are allowed, it is possible to allow blind transport format detection with flexible positions.

Several examples for how the blind transport format detection with flexible positions might be performed are:

- The blind transport format detection starts at a fixed position and identifies the transport format of the first present transport channel and stops. The position of the other transport channels and their transport format being derived on the basis of the allowed transport format combinations, assuming that there is a one to one relationship between the transport format combination and the transport format of the first present transport channel.
- The blind rate detection evaluates all transport format combinations and picks the most reliable one.

Figure A-2: Basic processing flow of blind transport format detection

## 5 History

<b>Document history</b>		
V0.0.1	1999-02-12	First version created by the editor on the basis of XX.04 and the Volume 3 of the ARIB specification.
V0.1.0	1999-02-26	Version approved by WG1#2 meeting (Yokohama). The changes agreed at the meeting to incorporate e.g. Ad Hoc conclusions not yet included.
V1.0.0	1999-03-05	Version approved by RAN. Identical to V0.1.0
V1.0.1	1999-03-17	Document updated based on Ad Hoc conclusions and comments at the WG1#2 meeting (Yokohama). Editorial changes also included.
V1.0.2	1999-03-23	Document updated based on Ad Hoc conclusions at the WG1#3 meeting. Editorial changes and corrections of mistake also included.
V1.0.3	1999-03-25	Document updated based on comments at the WG1#3 meeting. Editorial changes also included.
V1.1.0	1999-03-26	Version approved by WG1#3 meeting (Nynashamn). Identical to V1.0.3
V1.1.1	1999-04-19	Document updated based on text proposals approved in WG1#4 Day 1.
V1.1.2	1999-04-20	Document updated based on text proposals approved in WG1#4 Day 2.
V2.0.0	1999-04-20	Version approved by WG1#4 meeting (Yokohama).
V2.0.1	1999-04-22	This is a results from the drafting group in RAN#3 based on the comments received.
TS 25.212 V1.0.0	1999-04-22	Noted by TSG-RAN as TS 25.212 V1.0.0
