

3GPP TSG-RAN WG1#86

R1-167977

Gothenburg, Sweden, August 22 – 26, 2016

SOURCE: ERICSSON

TITLE: OVERHEAD REDUCTION FOR  
CLASS B CSI-RS

AGENDA ITEM: 7.2.4.1.2

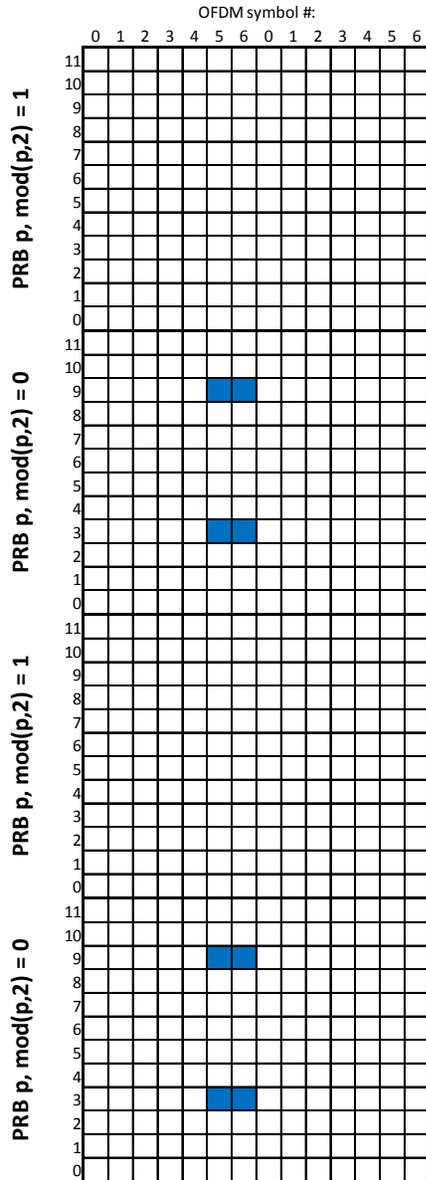

DOCUMENT FOR: DISCUSSION AND  
DECISION

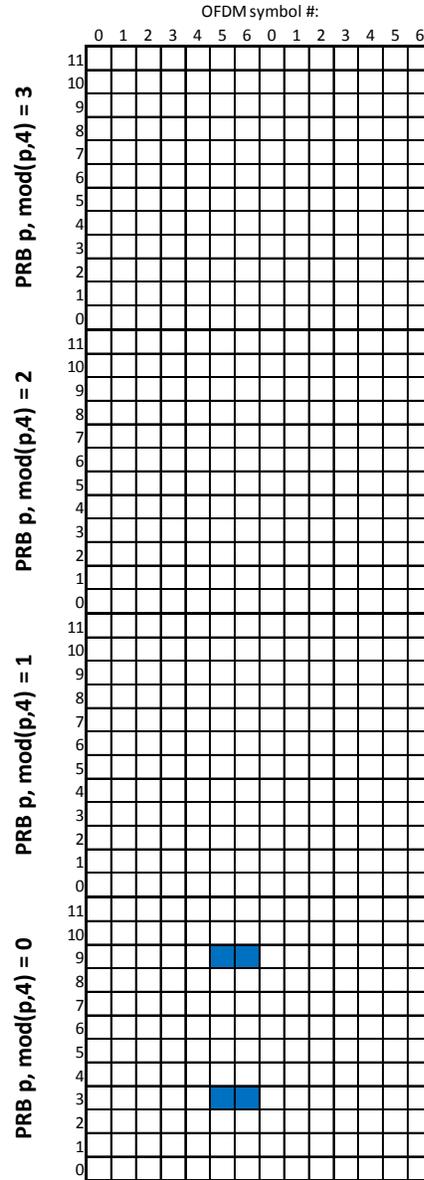

# BACKGROUND

- › In RAN1#85, the following conclusion was made with regards to overhead reduction for Class B CSI-RS
- › Candidate schemes for CSI-RS overhead reduction for Class B eMIMO-Type (2, 4, and 8 ports):
  - Scheme 1: Configurable CSI-RS frequency-domain density
  - Scheme 2: Localized CSI-RS in frequency domain
  - Scheme 3: Configurable RPF pattern
  - Scheme 4: Frequency domain MR
- › Companies are encouraged to study the following issues in the next meeting:
  - Backward compatibility
  - UE implementation restriction (for, e.g. channel estimation)
  - Impact on eNB scheduling
  - Impact on CSI reporting
  - PDSCH rate matching
- › In this contribution, we present system simulation results and our views on the different candidate schemes identified above.
- › Results are presented for different frequency domain overhead reduction (FDOR) configurations.

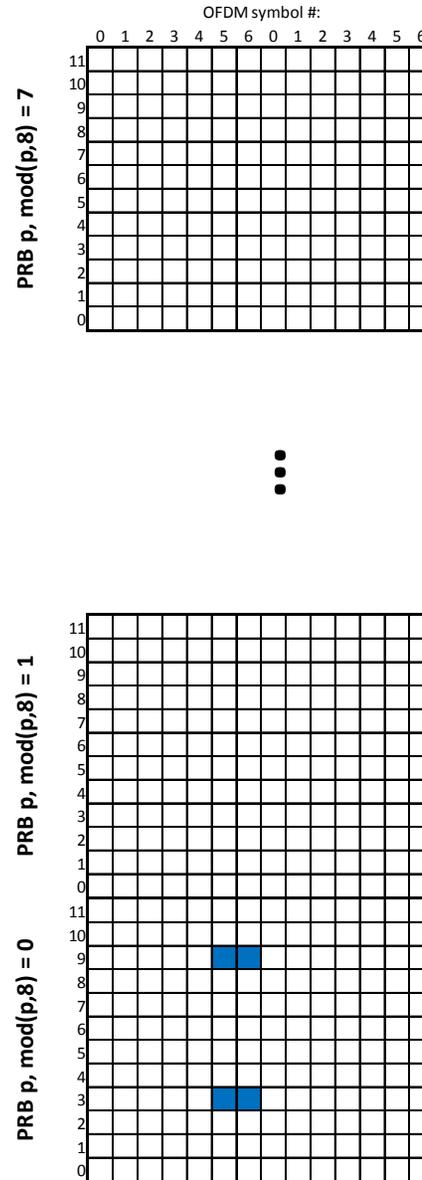

# CLASS B CSI-RS WITH DIFFERENT DENSITIES

**FDOR Config 1** 0.5 RE/RB/port

**FDOR Config 2** 0.25 RE/RB/port

**FDOR Config 3** 0.125 RE/RB/port

- › Three 4- port FDOR Config examples evaluated are shown here.
- › All ports are assumed to be in the same set of PRBs in these FDOR Config examples.

# COMPARISON WITH DIFFERENT DENSITIES

| Reference RU [%]                        | 20                                 |               |               |               | 43                                 |               |               |               |
|---|------------------------------------|---------------|---------------|---------------|------------------------------------|---------------|---------------|---------------|
| Reference offered traffic [bps/Hz/cell] | 0.6624                             |               |               |               | 1.1601                             |               |               |               |
|   | 4-port BF CSI-RS with 1 RE/RB/port | FDOR Config 1 | FDOR Config 2 | FDOR Config 3 | 4-port BF CSI-RS with 1 RE/RB/port | FDOR Config 1 | FDOR Config 2 | FDOR Config 3 |
| Cell edge throughput [bps/Hz/user]      | 1.2336                             |               |               |               | 0.6416                             |               |               |               |
| Mean throughput [bps/Hz/user]           | 3.6178                             |               |               |               | 2.6302                             |               |               |               |
| Cell edge gain [%]                      | 0                                  | 0             | -5            | -16           | 0                                  | -5            | -16           | -34           |
| Mean throughput gain [%]                | 0                                  | -1            | -1            | -5            | 0                                  | -1            | -6            | -14           |

FDOR Config 1 0.5 RE/RB/port

FDOR Config 2 0.25 RE/RB/port

FDOR Config 3 0.125 RE/RB/port

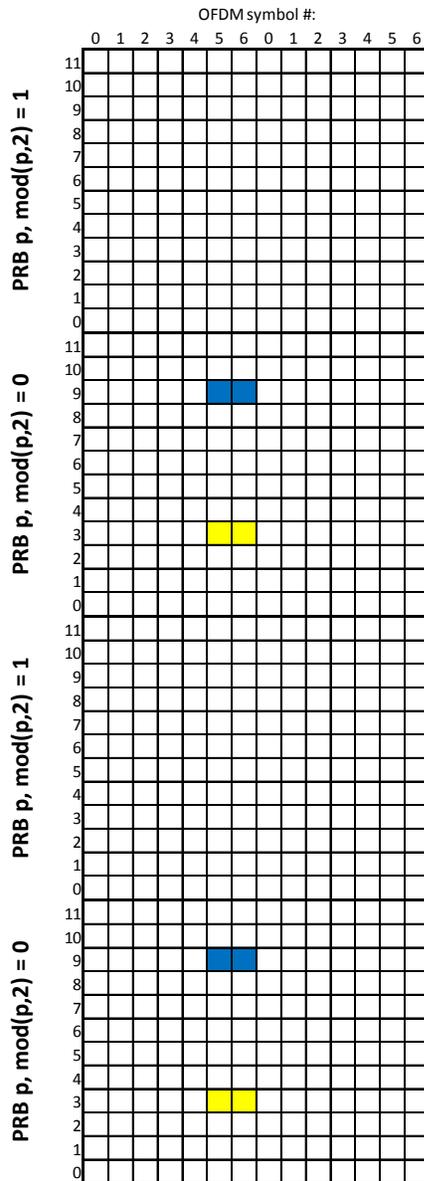

Sim Setup: 3D-UMa, 8x2 Array, Class B: 4 ports (1x2 Layout)

Observation 1: FDOR Config 1 with CSI-RS density 0.5 suffers very small losses compared to density 1.

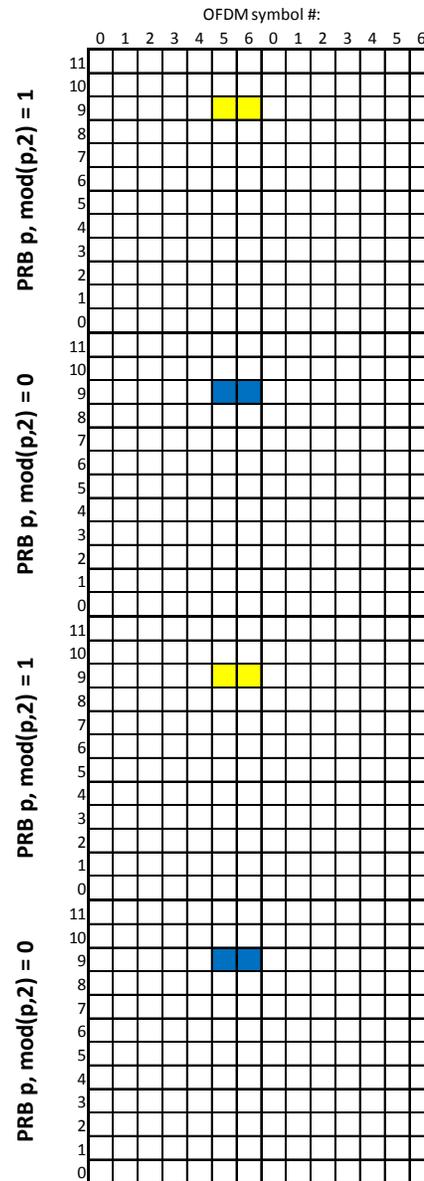

Observation 2: FDOR Config 3 with CSI-RS density 0.125 suffers notable losses compared to density 1.

Note: To realize gains due to overhead reduction in Class B CSI-RS, there should be a sufficiently large number of UEs present in a cell at the same time. With current FTP Model 1, it is difficult to realize this. Hence, our results only show how much the performance degrades with different CSI-RS densities.

# CLASS B CSI-RS WITH DIFFERENT PORT DISTRIBUTIONS

FDOR Config 1 0.5 RE/RB/port

FDOR Config 4 0.5 RE/RB/port

- Two different 4-port distributions with the same CSI-RS density are shown and compared.
- In FDOR Config 1, all ports are located in the same set of PRBs.
- In FDOR Config 4, different ports are located in different set of PRBs.

# COMPARISON WITH DIFFERENT PORT DISTRIBUTIONS

| Reference RU [%]                        | 20                                 |               |               | 43                                 |               |               |
|---|------------------------------------|---------------|---------------|------------------------------------|---------------|---------------|
| Reference offered traffic [bps/Hz/cell] | 0.6624                             |               |               | 1.1601                             |               |               |
|   | 4-port BF CSI-RS with 1 RE/RB/port | FDOR Config 1 | FDOR Config 4 | 4-port BF CSI-RS with 1 RE/RB/port | FDOR Config 1 | FDOR Config 4 |
| Cell edge throughput [bps/Hz/user]      | 1.2336                             |               |               | 0.6416                             |               |               |
| Mean throughput [bps/Hz/user]           | 3.6178                             |               |               | 2.6302                             |               |               |
| Cell edge gain [%]                      | 0                                  | 0             | -10           | 0                                  | -5            | -19           |
| Mean throughput gain [%]                | 0                                  | -1            | -2            | 0                                  | -1            | -7            |

FDOR Config 1

0.5 RE/RB/port, All ports in same RB

FDOR Config 4

0.5 RE/RB/port, Ports distributed in different RBs

Sim Setup: 3D-UMa, 8x2 Array, Class B: 4 ports (1x2 Layout)

Observation 3: FDOR configurations with all CSI-RS ports located in the same PRBs outperform FDOR configurations that distribute different set of ports in different PRBs.

- > When different ports are distributed in different PRBs, there is phase drift between ports which causes performance degradation

# DISCUSSION (1/3)

- › One way to realize FDOR configurations 1-4 is to use FDM with a configurable reduction factor (i.e., Schemes 1 and 3 of conclusions in RAN1#85)
  
- › For FDM configurations where all ports located in the same set of PRBs (e.g. FDOR Configs 1-3)
  - › Pros: Outperforms FDM configurations where different ports are distributed in different set of PRBs (e.g. FDOR Config 4).
  - › Cons:
    - a) PDSCH rate matching requires the definition of new ZP-CSI-RS configurations
    - b) When combined with Aperiodic NZP CSI-RS, may require additional bits in UL related DCI (depending on CSI-RS density)

# DISCUSSION (2/3)

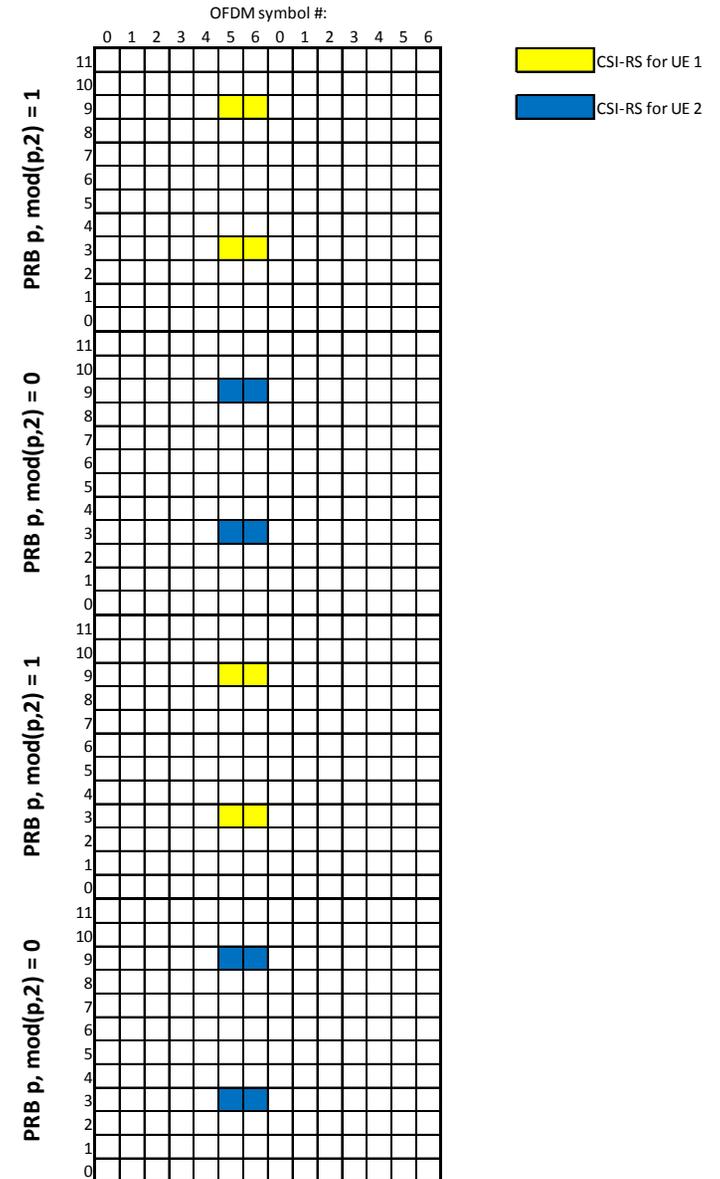

- › For FDM configurations where different ports are distributed in different set of PRBs
  - › Pros: For some configurations reduced density CSI-RS can be made to align with ZP CSI-RS of legacy UEs (as discussed in [1]).
  - › Cons:
    - a) Poorer performance than cases where all ports are located in the same set of PRBs due to phase drift issues.
    - b) When combined with Aperiodic NZP CSI-RS, may require additional bits in UL related DCI (depending on CSI-RS density)

# DISCUSSION (3/3)

- › Scheme 4 based on Frequency domain measurement restriction (FDMR) can alleviate the drawbacks of the Configurable FDM variants.
- › With FDMR, a UE can be requested to measure a set of CSI-RS ports on a set of PRBs, and where the UE assumes the CSI-RS occupies the full band.
  - › Hence, complex PDSCH rate matching issues are not needed.
  - › No need for defining reduced density ZP CSI-RS
  - › Compatible with legacy Rel-10 ZP CSI-RS configurations.
- › Example to the right shows, 4-port CSI-RS in even PRBs are measured by UE2 and 4-port CSI-RS in odd PRBs are measured by UE1.
  - › Both UEs rate match around both sets of CSI-RS.

# PROPOSAL:

- › Based on the observations and discussion we make the following proposals:
- › **Proposal 1: Overhead reduction for Class B CSI-RS should be considered in eFD-MIMO.**
- › **Proposal 2: Consider Frequency Domain Measurement Restriction for overhead reduction of Class B CSI-RS.**

# APPENDIX: SIMULATION PARAMETERS

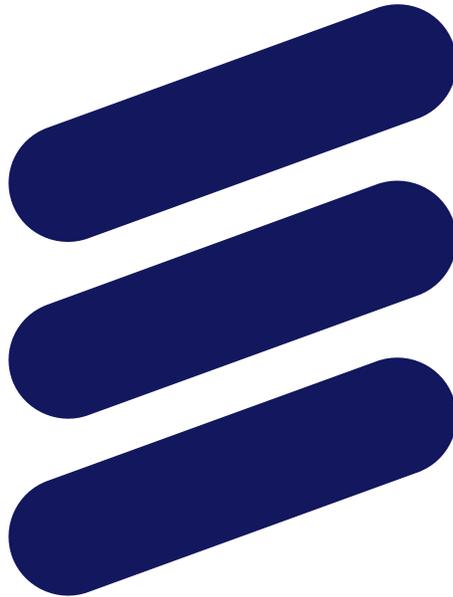

|                       |   |
|-----------------------|---|
| Carrier frequency     | 2 GHz   |
| Bandwidth             | 10 MHz  |
| Scenarios             | 3D UMa 500m ISD   |
| Antenna Configuration | 8x2 with 2x1 virtualization (121 degree tilt), Hybrid setup with 16 ports for Class A and 4 ports for Class B |
| Cell layout           | 57 homogeneous cells  |
| Wrapping              | Radio distance based  |
| UE receiver           | MMSE-IRC  |
| CSI periodicity       | Class B: 5 ms, Class A: 80 ms   |
| CSI delay             | 5 ms  |
| CSI mode              | Aperiodic mode 3-2  |
| Outer loop LA         | Yes, 10% BLER target  |
| eNB Tx power          | 46dBm   |
| Traffic model         | FTP Model 1, 500 kB packet size   |
| UE speed              | 3 km/h  |
| UE noise figure       | 9dB   |
| Scheduling            | Proportional fair in time and frequency   |
| Transmission Mode     | TM10 with non-shifted CRS   |
| DMRS overhead         | 2 antenna ports   |
| CSI-RS                | Overhead accounted for; channel estimation error modeled  |
| HARQ                  | Max 5 retransmissions   |
| Antenna spacing       | 0.8 lambda in vertical, 0.5 lambda in horizontal  |
| Handover margin       | 3 dB  |
