# Foreword

This Technical Report has been produced by the 3GPP.

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of this TS, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

7

Version 3.y.z

where:

- x the first digit:
  - 1 presented to TSG for information;
  - 2 presented to TSG for approval;
  - 3 Indicates TSG approved document under change control.
- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
- z the third digit is incremented when editorial only changes have been incorporated in the specification.

## 1 Scope

This Technical Report describes the 1.28Mcps functionality for UTRA TDD physical layer, identifies commonalties and explains the differences to the 3.84Mcps chip rate. Suggestions for alignment will be provided too.

# 2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- ?? References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- ?? For a specific reference, subsequent revisions do not apply.
- ?? For a non-specific reference, the latest version applies.

# 4 Radio Requirements

### 4.1 Radio environments

The radio environment recommended by ITU like indoor environment, pedestrian environment, vehicular environment (120km/h) should be well supported by the low chip rate TDD option.

### 4.2 Services

As one option of TDD mode, the low chip rate option should provide the basic service (bearer service). For a IMT-2000 compliant system corresponding to ITU requirement, for the indoor environment, up to 2Mbps data service should be provided. And for outdoor pedestrian environment, the data service should be up to 384kbps and more. For the UE in moving environment (vehicular speed less than 120km/h), the data rate supported should be 384 and more kbps.

### 4.3 Operational requirements

The low chip rate TDD option should provide the flexibility to be used for high spot or high density area to provide high speed data service or to provide enhanced coverage or be used alone as macro cell to provide the service coverage. It should allow deployment together with FDD system, with high chip rate TDD system, and be similar as high chip rate TDD deploying with GSM.

### 4.3.1 Deployment scenarios

For the low chip rate TDD option, the deployment should be flexible for all the scenarios like macro cell, micro cell and pico cell, etc. and also should provide the fixed wireless access.

### [Description:]

For the low chip rate TDD option, the deployment should be flexible for all the scenarios like macro cell, micro cell and pico cell, etc. and also should provide the fixed wireless access.

Dependent on the kind of interference accepted by the operator, the operator can vary the max. cell radius in a trade-off with UL - DL interference with the following limitations:

Case	Max. cell radius
no UpPTS – DwPTS interference allowed	11.25 km
UpPTS – DwPTS interference allowed, but no interference to TS0 allowed	22.5 km
no TS1 – DwPTS interference allowed, other interference allowed	30 km
TS1 – DwPTS interference allowed, but no interference to TS0 allowed	41.25 km

Table: Interference scenarios and the corresponding max. cell radius

### [Rational:]

The guard period of 75 ?s between the DwPTS and the UpPTS is designed to avoid interference between the UpPTS (UL) and the DwPTS (DL). Therefore the cell size ensuring the interference free reception of the DwPTS is guaranteed to a size of approximately 10 km in radius (exact value 11.25 km, assuming no delay spread).

Consequently, for bigger cell radii there is a conflict that the advanced UpPTS interfering the DwPTS reception of another UE being close by.

Even though the UpPTS – DwPTS interference is possible for bigger cell radii then 11.25 km, the impact on the quality of service can be low and acceptable for an operator willing to operate bigger cells.

There are three reasons for that:

The probability that the a UE is close to another UE is low - especially for big cells

The DwPTS needs not to be received by every mobile in every frame. A few DwPTSs being not received during initial cell search mean no big degradation.

The UpPTS is not transmitted every frame it is only needed for random access or handover. So the probability of disturbance is rather low.

It is recommended that the operator avoids interference of TS1 to TS0 by means of the choice of the cell radius. This interference would mean permanent interference for TS0.

The operators can judge the trade-off between quality of service and range and select the range accordingly.

The maximum cell radius  $d_{max}$  is dependent on the time  $t_{gap}$  between the potentially interfering UL signal and the potentially interfered DL signal by to following equation:

$$d_{\max}$$
 ?  $\frac{c t_{gap}}{2}$ ; c is velocity of light.

The following table shows the possible trade-offs between cell radius and interference:

Potentially interfering UL signal	Potentially interfered DL signal	t <sub>gap</sub> in ? s	d <sub>max</sub> in km
UpPTS	DwPTS	75	11.25
UpPTS	TS0	150	22.5
TS1	DwPTS	200	30
TS1	TS0	275	41.25

Allowed cell radius for the occurrence of the special UL - DL interference

[Explanation difference:]

For the high chip rate option there is no DwPTS – guard – UpPTS structure. Here, the UL time slots are following the DL time slots immediately. Thus, there is only one step in degree and quality of interference between DL and UL signals.

For the low chip rate option, it makes a difference in quality and degree whether the DwPTS or TS is interfered by the UpPTS or TS1. Hence the trade-off between cell range and interference is more manifold for the low chip rate option.

### 4.4 Handover and Cell selection/reselection

The low chip rate TDD option should support the handover between UTRA modes (e.g, low chip rate TDD to high chip rate TDD, low chip rate TDD to FDD), and between systems (e.g. low chip rate TDD to GSM, etc.).

### 4.5 Particular characteristics of the low chip rate TDD

The features of uplink synchronization, smart antenna (beam forming) etc. have been discussed. These features were agreed to be included in this technical report as they may provide potential perfomance improvement.

# 6 Physical layer - General description

### 6.1 General description of Layer 1

Common with the high chip rate TDD mode

### 6.1.2 Service provided to higher layers

The physical layer offers data transport services to higher layers. The access to these services is through the use of transport channels via the MAC sub-layer. In addition to the functions listed in TS25.201, the physical layer for the low chip rate TDD option is expected to perform the following functions in order to provide the data transport service:

- beamforming
- synchronisation shift control

### 6.2 Document structure of the physical layer specification

### 6.2.1 Multiple Access

In contrast to the high chip rate TDD option, the access scheme is Direct-Sequence Code Division Multiple Access (DS-CDMA) with information spread over approximately 1.6 MHz bandwidth only, thus also often denoted as low chip rate TDD option due that nature.

The frame structure of the low chip rate options differs from the high chip rate option in the following way: A 10 ms radio frame is divided into 2 sub-frames of 5ms. The frame structure (e.g. switching points) for each sub-frame in the 10ms frame length is the same. The sub-frame is divided into 7 traffic slots (864 chip/slot at the chip rate 1.28 Mcps) as described in subclause 7.2.1 'Frame Structure' and 3 timeslots with special functionality.

The information rate of the channel is different from the high chip rate option and varies with the symbol rate being derived from the 1.28 Mcps chip rate, the spreading factor and the modulation mode.

### 6.2.2 Channel coding and interleaving

Common with the high chip rate TDD mode

### 6.2.3 Modulation and spreading

The ordinary modulation scheme is QPSK, as for the the high chip rate option. In addition to that 8PSK is also possible.

For separating different cells the following solutions are additionally supported in the low chip rate option:

- SYNC sequences, SYNC1 sequences.

For separating different UEs the following code families are additionally defined:

SYNC1 sequences

### 6.2.4 Physical layer procedures

There are several physical layer procedures involved with low chip rate TDD operation that are different and in addition to the high chip rate option. Such procedures covered by physical layer description are:

- 1) The power control, for low chip rate TDD mode close loop control in both uplink and downlink.
- 2) Cell search operation.
- 3) Uplink synchronisation for low chip rate TDD mode.
- 4) Random access
- 5) Beamforming (optional)

### 6.2.5 Physical layer measurements

Common with the high chip rate TDD mode

#### [Explanation difference to section 6]

Most of the physical characters of the low chip rate TDD option are same as the high chip rate TDD option. But due to the different operation frequency band width and some other different implementation consideration such as power control method, uplink synchronization, there still exist some difference and all these differences will be discussed in the main part of TR25.928.

# 7 Physical channels and mapping of transport channels onto physical channels

- 7.1 Transport channels
- 7.1.1 Transport channels

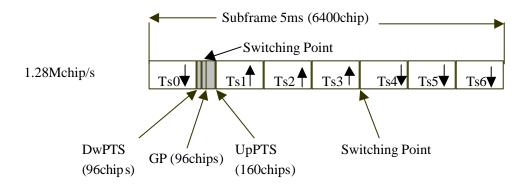

'Common with the high chip rate TDD mode'

### 7.2 Physical channels

### 7.2.1 Frame structure

[Description:]

For low chip rate option, the frame length is 10ms and the 10ms frame is divided into 2 sub-frames of 5ms. The frame structure for each sub-frame in the 10ms frame length is the same.

The frame structure for each sub-frame is shown in Figure above.

Figure Structure of the sub-frame for low chip rate option

Tsn (n from 0 to 6): the nth normal time slot, 864 chips duration;

DwPTS: downlink pilot time slot, 96 chips duration;

UpPTS: uplink pilot time slot, 160 chips duration;

GP: main guard period for TDD operation, 96 chips duration;

#### [Rationale:]

In the figure above, the total number of normal traffic time slot for uplink and downlink is 7, and the length for each normal time slot is 864 chips duration. Among the 7 normal traffic time slot, Ts0 is always allocated as downlink while Ts1 is always allocated as uplink. The time slots for the uplink and the downlink are separated by a switching point. Between the downlink time slots and uplink time slots, the special period is the switching

point to separate the uplink and downlink. In each sub-frame of 5ms for low chip rate option, there are two switching points (uplink to downlink and vice versa). The proposed frame structure has taken some new technologies into consideration, either the smart antenna (beam forming) technology or the uplink synchronisation will be well supported.

Using the above frame structure, the low chip rate TDD option can operate on both symmetric and asymmetric mode by properly configuring the number of downlink and uplink time slots; (note that whatever the time slot configuration will be, the GP and DwPTS position within the frame should not change in order not to desynchronise the UEs and in order to allow Node B on air synchronisation procedures which make use of the DwPTS channel!) . It should be noted that in asymmetric operation mode, at least one normal uplink time slot and one downlink time slot will be allocated for traffic (Ts0 for downlink and Ts1 for uplink). The guard period GP of 96 chips can support the cell radius of up to about 11 km for uplink synchronization operation where the uplink transmission is advanced in macro-, micro- and pico- cell of small cells in cities or large cells in rural areas. Here the GP insures that an UE transmitting the UpPTS does not disturb the reception of the DwPTS for other UEs being close by. If this distortion is accepted in the network the cell radius can be bigger. (Note that the UpPTS is not continuously transmitted and the DwPTS is not continuously received.)

The only difference to the last version of the frame structure proposal for low chip rate is the improving of the numbering of the time slots. The physical layer behaviour does not change.

#### [Explanation of difference:]

For both high chip rate option and low chip rate option, the frame length is 10 ms, But for low chip rate option the 10 ms length is divided into 2 sub-frame of 5 ms to allow the fast update of power control, uplink synchronization, and smart antenna beamforming.

For high chip rate option , each 10 ms frame consists of 15 time slots, each allocated to either the uplink or the downlink . So it has both single and multiple-switching point configuration both for symmetric and asymmetric allocation. While in the low chip rate option, the position of the big Guard Period GP and of the DwPTS and UpPTS physical channels, is always between Ts0 and Ts1 whatever the level of asymmetry be.

### 7.2.2 Dedicated physical channel (DPCH)

### 7.2.2.1 Spreading

'Common with the high chip rate TDD mode'

### 7.2.2.2 Burst Types

[Description:]

In correspondence to the frame structure described above, the burst structures for Tsn, DwPTS and UpPTS are proposed. The burst structure for normal time slot (Tsn) is described in Figure below.

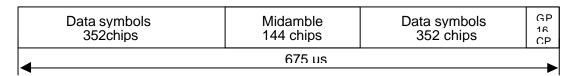

Figure Burst structure for normal traffic time slot

The structure for DwPTS and UpPTS is described in Figures below.

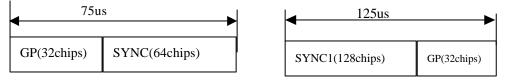

Figure Structure for DwPTS

Figure Structure for UpPTS

[Rationale:]

In the burst structure figure, the data symbols in each side of the midamble are 352 chips. The TPC bits for power control, the TFCI bits and the additional uplink synchronization bits (synchronization shift) are included in the Data symbols fields of the burst if they are needed. The amount of TFCI bits used is depending on the service and the details for TFCI, synchronization shift and TPC bits should be provided later with service mapping. For the power control symbols, the uplink synchronization control symbols and the TFCI the symbols around the midamble are used.

The GP field in the same figure for each time slot is used for protection between time slots to avoid the long delay multi-path interference. It should be noted that the GP of the TS0 together with the guard period in DwPTS is 48 chips long which is different with other normal guard period of 16 chips between time slots. This 'super long' guard period can be used to avoid the interference between the last normal downlink time slot and the downlink synchronization pilot burst. Otherwise, the interference to the last downlink time slot from the strong powered pilot will be serious to the traffic; and vice versa, the interference to the downlink pilot burst from the last downlink time slot will decrease the performance on downlink synchronization and cell search. Note that if the UEs serving Node B is far away and the UE makes handover measurements it will receive the beginning of the DwPTS of a close by Node B inside these 48 chip. 48 chip corresponds to 11 km difference in distance to the Node B. If the other Node B is more distant to the serving Node B, big guard period can be used for receiving the DwPTS of the handover candidate Node B.

In DwPTS and UpPTS, the content of SYNC and SYNC1 field are used for downlink and uplink pilot. The GP fields are used to separate the downlink (uplink) pilot from the normal downlink (uplink) time slot.

It should be pointed out that the uplink synchronization burst (SYNC1) is not followed by a RACH immediately. First the UL synchronization burst UpPTS is sent by the UE. This UpPTS is used for Node B to determine the received power level and the received timing. Second, the Node B transmits timing and power control information to the UE using the FPACH (one burst message) within the next 4 frames. Then the P-RACH is transmitted. Both FPACH and P-RACH are carrying single burst messages transmitted on a normal traffic time slot (see Burst structure figure). This two phase procedure which is different with the GSM of one phase procedure has better performance than the classical approach as used in GSM. In this case, the normal traffic burst and access burst can be active in the same time slot and the interference is reduced for each other if they are time-aligned.

Note that the UpPTS has to be transmitted by the UE in advance (staring in the big GP) to arrive at the Node B at the position indicated in the burst structure figure. The UpPTS can also be received at a different position if the UE cannot or does not aim at the RX position indicated in the burst structure figure. Thus, the UpPTS can also start within the guard interval (RX, TX), depending on the situation in the system. This means relaxation to estimate timing in UE, e.g. from pathloss on P-CCPCH.

And the proposed frame structure can support all the environments of macro-, micro- and pico- cells. In vehicular environment, the speed can be more than 120km/h. Also in the proposed frame structure, some specific properties for low chip rate option such as smart antenna technology, uplink synchronisation, beamforming, etc can be well supported.

[Explanation difference:]

In high chip rate option, there are 2 burst types of DPCH. They have different midamble lengths. And there is only one burst type of DPCH in the low chip rate option. The use of the same burst structure for RACH and for traffic will guarantee that the RACH can be handled with conventional traffic on the same UL time slots since the RACH is already UL synchronised.

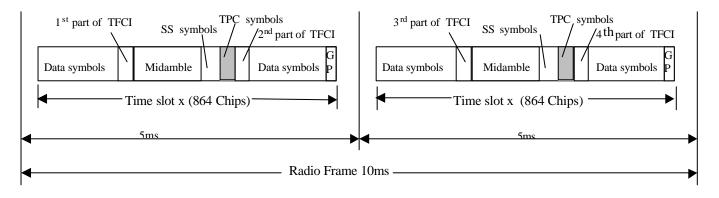

### 7.2.2.2.1 Transmission of TFCI

[Description:]

There is only one burst type for normal time slot in the low chip rate option. It provides the possibility for transmission of TFCI both in up- and downlink. For every user the TFCI information is to be transmitted once per 10ms radioframe. If no TPC and SS are applied, the TFCI information is to be transmitted directly adjacent to the midamble of the 5ms subframe of the assigned frame. The position in case of TPC and/or SS application is shown in the figures below.

#### [Rationale:]

There is only one burst type for normal time slot in the low chip rate option. It provides the possibility for transmission of TFCI both in up- and downlink. For every user the TFCI information is to be transmitted once per 10ms radioframe. The transmission of TFCI is negotiated at call setup and can be re-negotiated during the call. For each CCTrCH it is indicated by higher layer signalling, which TFCI format is applied. Additionally for each allocated timeslot it is signalled individually whether that timeslot carries the TFCI or not. If a time slot contains the TFCI, then it is always transmitted using the first allocated channelisation code in the timeslot, according to

#### Position of TFCI information in the traffic burst in case of L1 control signals

#### the order in the higher

layer allocation message. The transmission of TFCI is done in the data parts of the respective physical channel, this means TFCI and data bits are subject to the same spreading procedure. The encoded TFCI symbols are both equally distributed between the subframes and between the data blocks. Hence the midamble structure and length is not changed. If no TPC and SS are applied, the TFCI information is to be transmitted directly adjacent to the midamble of the 5ms subframe of the assigned frame. The position in case of TPC and/or SS application is shown in the figures above. Figure above shows the position of the TFCI in a traffic burst, if L1 control signals, SS (synchronization shift) and TPC (Transmit Power Control), is transmitted.

#### [Explanation difference:]

In high chip rate option, both burst types 1 and 2 provide the possibility for transmission of TFCI both in up- and downlink. The TFCI information is to be transmitted directly adjacent to the midamble if no TPC is transmitted. In the low chip rate option, there is only one burst type for normal time slot. It provides the possibility for transmission of TFCI both in up- and downlink. For every user the TFCI information is to be transmitted once per 10ms radioframe. The TFCI information is to be transmitted directly adjacent to the midamble of the 5ms subframe of the assigned frame if no TPC and SS is applied. The position of the TFCI in case of TPC and/or SS transmission is analogous to the high chiprate option and depicted in figure above.

### 7.2.2.2.2 Transmission of TPC

#### [Description:]

There is only one burst type for normal time slot in the low chip rate option. It provides the possibility for transmission of L1 control signal "TPC" both in up- and downlink. For every user the TPC information is to be transmitted once per 5ms subframe.

[Rational:]

Hence the midamble structure and length is not changed. The TPC information is to be transmitted directly after SS. Figure below shows the position of the TPC in a traffic burst.

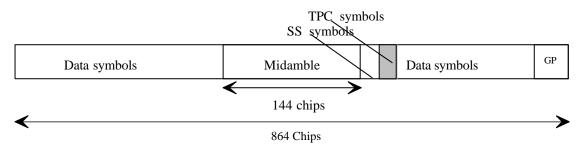

Figure : Position of TPC information in the traffic burst

For the number of layer 1 symbols there are 3 possibilities configurable for each channelisation code during the call setup:

- ?? one SS and TPC symbol
- ?? no SS and TPC symbols
- ?? 16/SF SS and 16/SF TPC symbols (note: there is a need to study this further)

### [Explanation difference:]

In high chip rate option, both burst types 1 and 2 provide the possibility for transmission of TPC only in uplink.

While in the low chip rate option, there is only one burst type for normal time slot. For the number of layer 1 symbols there are 3 possibilities configurable for each channelisation code during the call setup. It provides the possibility for transmission of TPC both in up- and downlink. For every user the TPC information is to be transmitted once per 5ms subframe. So it gives faster power control functionality in the low chip rate option than it does in high chip rate option. This is advantageous, because the lower chip rate has less frequency diversity which can be compensated with faster control algorithms. The smart antenna feature increases the demand on the speed of the control algorithms, because the smart antenna algorithms tend to focus on one DOA which has more Rayleigh fading than all DOAs received at a single antenna.

Note: This is to be verified by performance analysis

7.2.2.2.3 Timeslot formats

[Description:]

The timeslot format depends on the spreading factor, midamble length, the TPC and SS signals presence and on the number of the TFCI bits. In the case that L1 signals is used, different amount of bits are mapped to the two data fields. For the transmission of the TPC/SS, there are three possible configurations for the number of TPC/SS symbols:

- 1. 1 symbol TPC and 1 symbol SS
- 2. No TPC and No SS.
- 3. 16/SF symbol TPC and 16/SF symbol SS.

So, in case 3, when SF=1, the number of TPC/SS is 16 symbol corresponding 32 bits (for QPSK) and 48 bits (for 8PSK).

16/SF TPC/SS symbols is for the case that the number of L1 signalling bits of one given RU after spreading are same although different SFs are used. Thus, the mapping of user data on the payload can stay the same regardless what the spreading factor is.

The timeslot formats are depicted in the following subclause.

24	16	144	48	3&3	132	78	42	36

[Explanation difference:]

Based on the burst structure and the TFCI,SS and TPC control signals, the low chip rate TDD option has a different burst type from that of high chip rate TDD option. When 2M service is transmitted, the timeslot formats are based on 8PSK modulation, but the timeslot formats in table 3 are not restricted to the use for 2Mbps only.

### 7.2.2.2.3 Transmission of SS

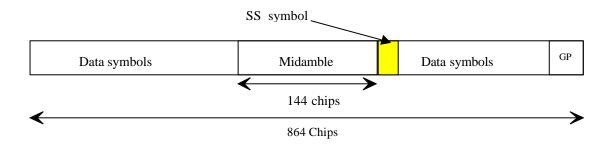

[Description:]

The SS is utilized to command a timing adjustment each M frame. The SS, as one of L1 signals, is to be transmitted once per 5ms subframe in downlink.

#### [Rationale:]

The SS is utilized to command a timing adjustment (k/8)Tc each M frames, where Tc is the chip period. The default k and M values are signaled by the network by means of system information that is broadcast in the cell. The SS information is to be transmitted directly after the midamble in downlink. Figure 1 shows the position of the SS in a burst. The SS, as one of L1 signals, is to be transmitted once per 5ms subframe.

M (1-8) and k (1-8) can be adjusted during call setup or readjusted during the call.

Position of SS information in a burst in downlink and uplink

Note that for the uplink where there's no SS symbol used, the SS symbol space is reserved for future use. This can keep the UL and DL slot same structure.

For the number of layer 1 symbols there are 3 possibilities configurable for each channelisation code during the call setup:

- ?? one SS and TPC symbol
- ?? no SS and TPC symbols
- ?? 16/SF SS and 16/SF TPC symbols

#### [Explanation difference:]

In high chip rate TDD option, SS information is not transmitted as L1 signal on each frame. Because of uplink synchronization in the low chip rate TDD option, SS information is transmitted in downlink, as one of L1 signals, once per 5ms subframe.

### 7.2.2.3 Training sequences for spread bursts

#### [Description:]

The training sequences, i.e. midambles, of different users active in the same time slot are time shifted versions of a single periodic basic code. Different cells use different periodic basic midamble codes, i.e. different midamble sets. In this way joint channel estimation for the channel impulse responses of all active users within one time slot can be done by one single cyclic correlation. The different user specific channel impulse response estimations are obtained sequentially in time at the output of the correlator.

Up to 16 midambles are possible within the low chip rate TDD option.

The generation of midamble is different from high chip rate TDD option. The difference of training sequences for spread bursts for low chip rate is described here.

#### [Rationale:]

The burst structure for low chip rate TDD option is different with high chip rate TDD option. These bursts contain  $L_m$  midamble chips, which are also termed midamble elements. The Lm elements  $\underline{m}_i^{(k)}$ ; i=1...Lm; k=1,...,K; of the midamble codes  $\underline{\mathbf{m}}_i^{(k)}$ ; k=1,...,K; of the K users are taken from the complex set

$$\underline{\mathbf{V}}_{\mathrm{m}} = ?1, j, -1, -j?.$$
 (1)

The elements  $\underline{m}_{i}^{(k)}$  of the complex midamble codes  $\underline{\mathbf{m}}^{(k)}$  fulfil the relation

$$\underline{m}_{i}^{(k)}?(\mathbf{j})^{i}?m_{i}^{(k)}m_{i}^{(k)}??\mathbf{1},?\mathbf{1}^{k};i?\mathbf{1},...,L_{m};k?\mathbf{1},...,K. (2)$$

Hence, the elements  $\underline{m}_{i}^{(k)}$  of the complex midamble codes  $\underline{\mathbf{m}}^{(k)}$  of the K users are alternating real and imaginary.

With W being the number of taps of the impulse response of the UE radio channels, the Lm binary elements  $m_i^{(k)}$ ;  $i = 1, ..., L_m$ ; k ? 1, ..., K; of (2) for the complex midamble  $\underline{\mathbf{m}}^{(k)}$ ; k=1, ..., K; of the K users are generated according to Steiner's method [1] from a single periodic basic code

$$\mathbf{m} ? \, \mathcal{M}_{1}, m_{2}, \dots, m_{L_{m}?(K?1)W} \, \mathcal{T} \, m_{i} ? \, \mathcal{H}, ? \, \mathcal{H}; \, i ? \, 1, \dots, (L_{m}?(K?1)W).$$
(3)

The elements  $m_i$ ; i? 1,...,  $(L_m$ ? (K? 1)W), of (3) fulfil the relation

 $m_i ? m_{i?P}$  for the subset  $i ? (P ? 1), ..., (L_m ? (K ? 1)W).$  (4)

The P elements  $m_i$ ; *i* ? 1,..., *P*, of one period of m according to (3) are contained in the vector

$$\mathbf{m}_{\mathrm{P}} ? ? m_1, m_2, \dots, m_P ? .$$
(5)

With **m** according to (3) the Lm binary elements  $m_i^{(k)}$ ; i = 1,..., L<sub>m</sub>; k ? 1,..., K; of (2) for the midamble of the K users are generated based on Steiner's formula

$$m_i^{(k)} ? m_{i?(K?k)W} i ? 1, ..., L_m; k ? 1, ..., K.$$
 (6)

In the following the term 'a midamble code set' or 'a midamble code family' denotes K specific midamble codes  $\underline{\mathbf{m}}^{(k)}$ ; k=1,...,K. Different midamble code sets  $\underline{\mathbf{m}}^{(k)}$ ; k=1,...,K; are in the following specified based on different periods  $\mathbf{m}_{p}$  according (5).

In adjacent cells of the cellular UE radio system, different midamble codes sets  $\mathbf{\underline{m}}^{(k)}$ ; k=1,...,K; should be used to guarantee a proper channel estimation.

As mentioned above a single midamble code set  $\underline{\mathbf{m}}^{(k)}$ ; k=1,...,K; consisting of K midamble codes is based on a single period  $\mathbf{m}_{P}$  according to (5).

In the following several exemplary periods  $\mathbf{m}_{P}$  according (5) which can be used to generate different midamble code sets  $\mathbf{\underline{m}}^{(k)}$ ; k=1,...,K; will be listed in tables in a hexadecimal representation. As shown in the table below always 4 binary elements  $m_{i}$  are mapped on a single hexadecimal digit.

The mean degradation's which serve as a quality information of the periods  $\mathbf{m}_{\rm P}$  according to (5) and hence of the specified midamble code sets  $\underline{\mathbf{m}}^{(k)}$ ; k=1,...,K; will be also given.

4 binary elements $m_i$	Mapped on hexadecimal digit

[Explanation difference:]

The midamble used in the burst for low chip rate TDD is different from high chip rate TDD. And this is mainly coming from different chip rate and burst format. Different chip rate lead to different length of channel impulse response and the different length of training sequence (midamble).

The maximum channel impulse response is scalable. This evokes a different midamble generation scheme as used for high chip rate TDD.

7.2.2.3.1 Selection of length of channel impulse response

#### [Description:]

The training sequences, i.e. Midambles, of different users active in the same slot are time shifted versions of one single periodic basic code. Different cells use different periodic basic codes, i.e. different midamble sets. In this way a joint channel estimation for the channel impulse responses of all active users within one time slot can be done by one single cyclic correlation. The different user specific channel impulse response estimates are obtained sequentially in time at the output of the correlator. Up to 16 midambles in one time slot are possible within the low chip rate TDD option.

In both low and high chip rate systems, W, the length of the impulse response of the mobile radio channels, is an important parameter. There is only one burst type for normal time slot in the low chip rate TDD option, and the length of midambles is different from the high chip rate option, so the selection of W needs to be defined seperately.

[Rational:]

The midamble has a length of Lm=144, which is corresponding to:

K=2, 4, 6, 8, 10, 12, 14, 16, W= 
$$\frac{?P?}{?K?}$$
, P=128.

Note: that  $2x^2$  denotes the largest integer number less or equal to x.

Depending on the possible delay spread cells are configured to use midambles which are generated from the Basic Midamble Codes.

The cell configuration is broadcast on BCH.

### 7.2.2.4 Beamforming and Transmit Diversity

#### [Description:]

A smart antenna system is composed of an array of multiple antenna elements and coherent transceivers with advanced digital signal processing algorithms. Instead of a single fixed beam pattern from a traditional antenna, the smart antenna can dynamically generate multiple beam patterns, each of them is pointed to a particular UE, and such beam patterns can adapt to follow any UE intelligently. On the Rx side of Node B, such a

feature, i.e., spatial selective reception at the Node B can greatly minimize co-channel interference from the cochannel UEs at different locations, thus increase the Rx sensitivity and lead to higher capacity. It can also effectively incorporate multipath components to combat multipath fading. On the Tx side of Node B, intelligent spatially selective Tx (downlink) beamforming can also greatly reduce the interference to other co-channel UEs, then dramatically save the output power requirement and lead to higher capacity. It should be noted that this section only describes a preferred approach to beamforming, other high performance techniques may also be applicable.

The low chip rate option is mainly based on the smart antenna technology. Some main technical features of the low chip rate TDD option such as 5 ms sub-frame structure are based on the smart antenna request.

When DL beamforming or TX Diversity is used, at least for the resource units beamforming/Tx Diversity is applied to and which are allocated to dedicated channels, the resource units shall get one individual midamble per user or per resource unit according to midamble generation, even in DL.

#### [Rationale:]

The smart antenna array is composed of N antenna elements, N related feed cables and N coherent RF transceivers in RF part. By use of the A/D converters or D/A converters in analog baseband (ABB), the Rx and Tx analog signals are interfaced to the digital baseband (DBB) part over the high-speed data bus. In this model, all antenna elements related feed cables and coherent RF transceivers will be calibrated before operating.

#### Beamforming

For the Node B is equipped with smart antenna array and DBB DSP, when a signal comes from one UE within the coverage of the Node B, each antenna element and coherent RF receiver will get it. Because of the different location of the different antenna element, the phase of the Rx signal will be different. In case of multipath propagation, each path will come from different directions with different amplitude and delay. Then the Rx signal at each antenna element will show different phase and amplitude. After the front-end processing in RF part and A/D converters processing in ABB, digitized Rx signal with the phase and amplitude information will be sent to DSP in DBB part. After despreading in the DBB processor, the Rx data of each code channel may be obtained.

The purpose of smart antenna in uplink is to find the best  $E_b/I_0$  after the combination. Theoretically, spatial reception at Node B can add up all useful signals while canceling all multipath interference. The next step is to realise downlink beamforming. The Tx signal of the each code channel is got by some algorithms that enable  $E_c/I$ 

the UE to obtain the best  $E_b/I_0$ . In TDD system, because of the symmetrical performance in wave propagation, it is possible to directly use the spatial reception at Node B results to downlink beamforming.

#### Fast beamforming

It is always very important to reach fast beamforming to catch the time variation in mobile network. The Node B should have a in-time reaction to the fast changing beam patterns. And this is the reason that the TDD interval in low chip rate option is 5ms while 10ms in high chip rate option. This value is a compromise in considering both the number of time slots and the switching speed of RF components.

In smart antenna system, the BTS need receive the UpLink data first, then decide the UE's position, and then beamform to UE in Downlink, but the UE does not need to transmit regularly for the Node B to determine the antenna weights when it is in idle mode.

### [Explanation difference:]

For high chip rate option, the chapter about beamforming already exists.

Like the high chip rate option is that not only each user can get one midamble but also each resource allocated to that user can (but need not to) get an individual midamble. The benefit of this is that the signalling overhead is reduced.

# 7.2.3 Primary common control physical channel (P-CCPCH)

### 7.2.3.1 Primary common control physical channel (P-CCPCH)

The BCH as described in subclause 7.3.2 'Common Transport Channels' is mapped onto the Primary Common Control Physical Channels (P-CCPCH1 and P-CCPCH2). The position (time slot / code) of the P-CCPCHs is fixed in low chip rate TDD option, see subclause 7.3.2 'Common Transport Channels'. An encoded bit identifies whether the interleaving frame in the P-CCPCH contains a BCH (1) or not (0).

### 7.2.3.1.1 P-CCPCH Spreading

The P-CCPCHs use fixed spreading with a spreading factor SF = 16. The P-CCPCH1 and P-CCPCH2 always use channelisation code 0 and 1 respectively.

### 7.2.3.1.2 P-CCPCH Burst Types

Only one burst type in low chip rate option

### 7.2.3.1.3 P-CCPCH Training sequences

The training sequences, i.e. midambles, as described in the MA-generation chapter are used for the P CCPCHs. The basic midamble code m<sup>(1)</sup> is used for P-CCPCHs as training sequence.

As mentioned in sub clause of P-CCPCH in 25.928, P-CCPCHs are mapped onto first two code channels of Ts0 with spreading factor of 16. Other code channel in Ts0 should also use spreading factor of 16.

Each transport channel assigned in TS0 has channel impulse response estimation window of maximum length W=16 such that there are 8 midamble codes used for TS0.

Ts0 is configured in the following way: Each of the 8 midamble codes is assigned to 2 code channels of spreading factor 16. The first midamble code is assigned to the first 2 code channels of spreading factor 16. The next midamble code to the next 2 code channels of spreading factor 16 and so forth. The P-CCPCHs are assigned to the first midamble code. In order to provide flexibility, it is possible that the Node B uses – for channels other than P-CCPCHs - a certain midamble code assigned to only 1 code channel of spreading factor 16. In that case, the second code that is assigned to the same midambles is not used by another UE.

#### [Explanation difference:]

In high chip rate option, the P-CCPCH always contains only the BCH . The position (time slot / code) of the P-CCPCH is known from the Synchronisation Channel (SCH).

In low chip rate option, the P-CCPCH can also contain the PCH and FACH as well as the BCH. The P-CCPCHs are mapped onto two code channels of the DL time slot (time slot 0) which is followed by the DwPTS

Other methods for BCH indication and their compatibility with models in TSG RAN WG2 are to be considered.

There are two kinds of burst types in high chip option and the burst type 1 is used for the P-CCPCH.

There is only one burst type in the low chip rate option.

If both the uplink and downlink physical channels are work under the synchronization mode and if "smart antenna" method is used, the interference on P-CCPCH is thought to be very little in low chip rate TDD option. As a result, "Tx diversity" has not been considered currently to be applied in low chip rate TDD. As this may not hold in all cases, the Block STTD applied for P-CCPCH is to be studied.

### 7.2.3.2 Secondary common control physical channel (S-CCPCH)

PCH and FACH can be mapped onto one or more secondary common control physical channels (S-CCPCH). In this way the capacity of PCH and FACH can be adapted to the different requirements. The time slot and codes used for the S-CCPCH are broadcast via cell information. An encoded bit identifies that the interleaving frame in the S-CCPCH contains no BCH. This bit is always 0.

### 7.2.3.2.1 S-CCPCH Spreading

There are two S-CCPCHs (S-CCPCH 1 and S-CCPCH 2) mapped onto two codes of spreading factor 16. There can be also more than a single pair in use.

### 7.2.3.2.2 S-CCPCH Burst Types

Same as for the P-CCPCH

### 7.2.3.2.3 S-CCPCH Training sequences

The training sequences, i.e. midambles as described in the MA-generation chapter, are used for the S-CCPCH.

### 7.2.3.3 The physical random access channel (PRACH)

The RACH is mapped onto one or more uplink physical random access channels (PRACH). In such a way the capacity of the RACH can be flexibly scaled depending on the operators need.

### 7.2.3.3.1 PRACH Spreading

The uplink PRACH uses either spreading factor SF=16 or SF=8 as described in subclause 7.3.2.3 'The Random Access Channel (RACH)'. The PRACH configuration (time slot number and assigned spreading codes) is broadcast through the BCH information

### 7.2.3.3.2 PRACH Burst Types

The burst type used on the PRACH is the same as for a traffic channel.

### 7.2.3.3.3 PRACH Training sequences

The training sequences, i.e. midambles as described in the MA-generation chapter, are used for the PRACH.

### 7.2.3.3.4 Association between Training Sequences and Channelisation Codes

In the low chip rate TDD option there is a different concept for the RACH. Resource units on the traffic time slots are used for the random access channels. For this reason the PRACH is described and allocated as e.g. the DPCH. Thus, there is no additional association between training sequences and channelisation codes like in the high chip rate TDD option.

#### [Explanation difference:]

In subclause 10.6.2 "random access procedure", it has been mentioned that the random access procedure of low chip rate option has two-step approach. The SYNC1 word is used to carry out uplink synchronisation and to resolve the access collision. This two-step procedure enables the PRACH to be transmitted with high synchronisation precision as DPCH. So in low chip rate TDD option, the PRACH is uplink synchronized with other uplink traffic, the burst type used on the PRACH is the same as for DPCH while in high chip rate TDD option the burst type of the PRACH is a little different from that of DPCH.

### 7.2.3.4 The synchronisation channel (SCH)

### [Description:]

There are two dedicated physical synchronisation channels —DwPTS and UpPTS in each subframe of the low chip rate option as described in subclause 7.2.1 'Frame Structure' and 7.2.2.2 'Burst Types'.

#### [Rationale:]

The burst structures used for DwPTS and UpPTS are different from that used for other physical channels. The detailed description of the burst structure of DwPTS and UpPTS can be found in subclause 7.2.2.2 'Burst Types'.

As described in subclause 7.2.2.2 'Burst Types', there are no training sequences in DwPTS and UpPTS. The SYNC code in DwPTS and the SYNC1 code in UpPTS are not spread.

#### [Explanation difference:]

In low chip rate option, there are two dedicated Physical Synchronisation Channels, DwPTS for the down link synchronisation and UpPTS for the uplink synchronisation.

In high chip rate option, there is only one dedicated Physical Synchronisation Channel for down link synchronisation

### 7.2.3.5 Physical Uplink Shared Channel (PUSCH)

'Common with the high chip rate TDD mode'

### 7.2.3.6 Physical Downlink Shared Channel (PDSCH)

'Common with the high chip rate TDD mode'

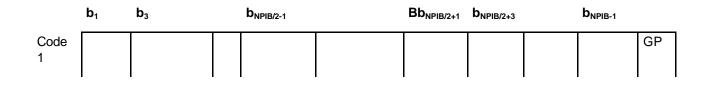

### 7.2.3.7 The Page Indicator Channel (PICH)

#### [Description:]

The Page Indicator Channel (PICH) is a physical channel used, as in 3.84 MCPS TDD option, to carry the Page Indicators (PI).

The PICH is transmitted time multiplexed with a P/S-CCPCH and it is sent at the same reference power level and with the same antenna pattern configuration as the P-CCPCH.

As in the 1.28 MCPS TDD option one burst type only is defined having a different structure with respect to the ones foreseen in the 3.84 MCPS TDD, the PICH structure will be different as well. The structure is chosen so that without defining reserved bits and for all possible PI lengths the bits corresponding to one PI can be symmetrically located in the time slot with respect to the midamble, as in 3.84 MCPS TDD. Moreover, the usage of two codes allows an easy time multiplexing with the P/S-CCPCH and about the same number of PIs per slot as in the 3.84 MCPS TDD mode. Figure below depicts the PICH structure and the numbering order of the transported bits,  $N_{PIB}$ , where  $N_{PIB}$  is equal to 176 bits.

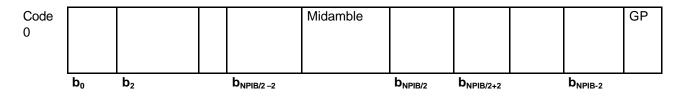

Figure: Transmission and numbering of PI carrying bits on the PICH

As in high chip rate TDD, Page Indicators can have different length ( $L_{Pl}$ ), where  $L_{Pl} = 2$  or 4 or 8 symbols respectively, as configured by the network. Therefore, the number of page indicators in a PICH burst are the ones reported in Table below.

Table : Number of Page Indicators (PI) in a PICH burst for the different PI length ( $P_{IL}$ )

	L <sub>Pl</sub> = 2	L <sub>Pl</sub> = 4	L <sub>Pl</sub> = 8
Number of PI per burst	44	22	11

Similar to the 3.84 MCPS TDD option, Page Indicators can be transmitted for  $N_{PICH}$  consecutive sub-frames, which form a PICH block as described in figure.  $N_{PICH}$  is configurable by the higher layers so that  $N = N_{PICH}*N_{PI}$  Page Indicators are transmitted in each PICH block.

### 1 PICH block

PI <sub>0</sub> ,, PI <sub>NPI-1</sub>	PI <sub>0</sub> ,, PI <sub>NPI-1</sub>	 PI <sub>0</sub> ,, PI <sub>NPI-1</sub>	PI <sub>0</sub> ,, PI <sub>NPI-1</sub>
Sub-Frame # i	Sub-Frame # (i+1)	 Sub-Frame #(i + NPICH –2)	Sub-Frame #(i + NPICH –1)

The structure of a paging block, consisting of a PICH and a PCH block is the same as in the high chip rate TDD option. As for the high chip rate TDD option, Page Indicator and Paging Group (PG) for a given user are computed by the higher layers in the network, where PI and PG are assigned independently one to the other.

A given PI corresponds to a PI<sub>P</sub> in the PICH burst of a PICH block at sub-frame number "n", according to the following rule:

 $p = PI \mod N_{PI};$ 

 $n = PI \text{ div } N_{PI}.$ 

As in the high chip rate TDD, the Page Indicator  $PI_P$  is mapped to two bit strings, where the first bit string consists of the bits ( $b_{LPI'P}$ ;...;  $b_{LPI'P+LPI-1}$ ) and the second bit string consists of the bits ( $b_{NPIB/2+LPI'P}$ ; ...;  $b_{NPIB/2+LPI'P+LPI-1}$ ) within that burst. This mapping scheme allows for an equal distribution of all PIs within the PICH burst.

[Rationale:]

PICH physical channel allows to improve the DRX mode at the UE, saving power consumption. The benefit of this channel have already been evaluated for the high chip rate TDD and FDD mode where it is now included; therefore it is recommended for its inclusion in the low chip rateTDD option as well.

[Differences:]

While no difference exits in principle between high chip rate TDD and low chip rateTDD PICH physical channel, there are differences in the burst structure coming from the different burst formats and the different number of supporting resource units in the respective TDD options.

7.2.4 Beacon function of physical channels

#### [Description:]

For the purpose of measurements, a beacon function shall be provided by particular physical channels. Considering about the physical character requirement of the beacon function, DwPTS and P-CCPCH in low chip rate TDD satisfy this requirement.

[Rationale:]

For the purpose of measurements, a beacon function is provided by the P-CCPCH and the DwPTS.

#### 7.2.4.1 Location of physical channels with beacon function

The DwPTS and the P-CCPCH provides the beacon function in low chip rate TDD.

### 7.2.4.2 Physical characteristics of the beacon function

The physical channels providing the beacon function:

- are transmitted with reference power;

are transmitted without beamforming

use midamble  $m^{(1)}$  exclusively in this time slot when P-CCPCH provide the beacon function

```
[Explanation difference:]
```

In high chip rate TDD, a beacon function has to be defined for channels other than the P-CCPCH, because there are two cases of synchronisation and the possibility of multiframes for the P-CCPCH.

In the low chip rate option, only the P-CCPCH and the DwPTS provide the beacon function.

### 7.2.5 Midamble Allocation for Physical Channels

'Common with the high chip rate TDD mode'

# 7.3 Mapping of transport channels to physical channels

[Description:]

This clause describes the way in which transport channels are mapped onto physical resources.

[Rational:]

Transport channels	Physical channels
DCH	Dedicated Physical Channel (DPCH)
ВСН	Primary Common Control Physical Channels (P-CCPCH)
PCH	Primary Common Control Physical Channels (P-CCPCH)
	Secondary Common Control Physical Channels(S-CCPCH)
FACH	Primary Common Control Physical Channels (P-CCPCH)
	Secondary Common Control Physical Channels(S-CCPCH)
RACH	Physical Random Access Channel (PRACH)
USCH	Physical Uplink Shared Channel (PUSCH)
DSCH	Physical Downlink Shared Channel (PDSCH)
	Down link Pilot Time Slot (DwPTS)
	Up link Pilot Time Slot (UpPTS)
	FPACH

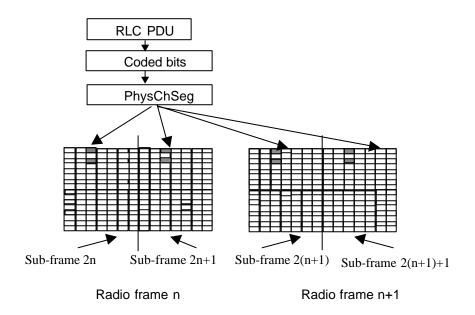

### Transport channel to physical channel mapping

[Explanation difference:]

The PCH and FACH can be mapped on P-CCPCHs and S-CCPCHs in low chip rate TDD option and the BCH will only mapped into P-CCPCHs. The dedicated physical channel of DwPTS and UpPTS are used for downlink and uplink pilot. The physical channel FPACH is used to answer the UE and to adjust the timing and synchronization shift of the UE. These three channels are used for synchronization operation. For a detailed description, see subclause 7.3.2 of 25.928.

# 7.3.1 Dedicated Transport Channels

Figure : Mapping of PDU onto the physical bearer( TTI= 20ms )

### [Description:]

The figure shows the mapping of PDU onto physical bearer.

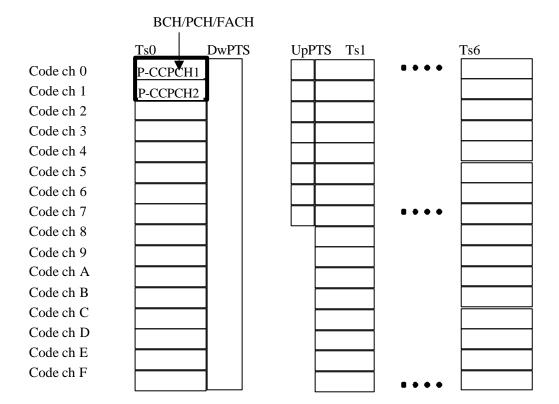

[Explanation difference:]

The mapping of PDU into dedicated channel is different from that of high chip rate TDD option according to the different frame structure. See separate sections (clause 8.1.11) for further explanation of the segmentation into sub-frames.

# 7.3.2 Common Transport Channels

[Description:]

The following figure shows the mapping of BCH, FACH and PCH transport channels onto the P-CCPCHs :

#### Figure Transport channels mapping onto the physical channels

In low chip rate option, There are two P-CCPCH, P-CCPCH 1 and P-CCPCH 2 which are mapped onto i channelisation codes 0 and 1 (spreading factor 16) A cell should always contain P-CCPCH 1 and P-CCPCH 2 The transport channels mapped onto the P-CCPCH shall effectively be mapped onto P-CCPCH 1 and P-CCPCH 2 using the multi-code function in the channel coding and multiplexing (See physical channel segmentation in 25.222). As far as the SCCPCH is concerned, two cases can be considered. Either there are as well two SCCPCH, S-CCPCH 1 and SCCPCH 2mapped onto two codes of spreading factor 16 or there is a single SCCPCH corresponding to a single code of spreading factor 8. The SCCPCHs may be mapped on any DL time slot. (as show in the figure above). More details are giving as following:

The BCH is mapped on a pre-defined number of RUs/physical channels, so that the UE can unambiguously decode it. As it is for the TDD high chip rate option and for FDD mode, the low chip rate option as well foresees for one P-CCPCH only. On the combined P-CCPCH1+P-CCPCH2, different logical channels can be mapped according to the multi-frame structure.

[Rational:]

### 7.3.2.1 The Broadcast Channel (BCH)

The BCH is always mapped on the P-CCPCH1+P-CCPCH2. Due to the adoption of smart antenna, in order to provide the coverage of the whole cell, the P-CCPCHs must have in general higher transmission power level with omni-directional or sectorial pattern (without adaptive beamforming) compared with the other physical channels which can be adaptively beamformed. The BCH is time multiplexed with other channels in the multi-frame.

The UE can find the beginning of each block which is delivered on the P-CCPCHs; that is the beginning of the interleaving period, through the DwPTS sequence and its relative phase with respect to the P-CCPCHs midamble sequences. Each DwPTS can have 4 different phases and can be independently assigned by the

Node B. Several continues different phase DwPTSs's combination can indicate the BCH's position in the multiframe and the start position of the interleaving period. Also the beginning of the control multiframe can be detected from phase relations. To ensure correct decisions, an additional bit coded together with a BCH block, allows the UE to know the BCH interleaving block in P-CCPCHs.

### 7.3.2.2 The Paging Channel (PCH)

The PCH is a special broadcast channel used to page UEs from RNC. As mentioned above, it can also be mapped onto the P-CCPCHs time multiplexed with the BCH, FACH( see figure above), and, therefore, transmitted with the same power level and antenna pattern as those of the BCH. PCH, FACH and BCH will occupy their own blocks in the multi-frame structure. And this is the preferred way, in some condition, the PCH can be mapped onto a different physical channel (S-CCPCH or SCCPCH1+SCCPCH2, on any DL time slot but not on the codes used for the P-CCPCHs.), the location of PCH is indicated on the BCH.(This gives more flexibility to the system.)

### 7.3.2.2 The Forward Channel (FACH)

The FACH is used to carry control information to a mobile station when the system knows the location cell of the mobile station. The FACH may also carry short user packets. The FACH can be mapped onto the P-CCPCHs time multiplexed with the BCH and PCH, and, therefore, transmitted with the same power level and antenna pattern as those of the BCH. PCH, FACH and BCH will occupy their own blocks in the multi-frame structure. And this is the preferred way, in some condition, the FACH can be mapped onto a different physical channel (S-CCPCH or SCCPCH1+SCCPCH2, on any DL time slot but not on the codes used for the P-CCPCHs.), the location of FACH is indicated on the BCH.(This gives more flexibility to the system.)

#### [Explanation difference:]

In high chip rate option, the BCH is always mapped onto P-CCPCH and the PCH/FACH onto the S-CCPCH. The P-CCPCH always contains only the BCH. The secondary SCH indicates in which timeslot a mobile can find the PCCPCH containing BCH. And the location of PCH is indicated on the BCH.

In low chip rate option, the BCH is mapped only onto the P-CCPCHs (Primary Common Control Physical CHannel). The P-CCPCHs can also contain the PCH and FACH as well as the BCH. The P-CCPCHs are mapped onto the DL time slot preceding the DwPTS using two codes of that time slot (as shown in the figure 1) as described above. According the frame structure, P-CCPCHs carrying the BCH is followed by DwPTS, so when the UE detects the SYNC word, it can immediately find the BCH.

### 7.3.2.3 The Random Access Channel (RACH)

### [Description:]

The RACH is mapped onto the P-RACH physical channel. The P-RACH configuration (time slot number and assigned spreading codes) is broadcast through the BCH information.

#### [Rationale:]

The RACH is mapped onto the P-RACH physical channel. The P-RACH can be configured by the network operator.

The P-RACHs can use either any spreading factor 16 RU or any spreading factor 8 RU in any UL time slot of the sub-frame. The spreading codes and time slots assigned to the P-RACHs are broadcast by the cell from the BCH. The capability of mapping RACH onto any UL time slot offers more flexibility to the system. The interference handling is then configurable. As the RACH is different from the other traffic it may be advantageous to distribute the RACH resources on several time slots.

The uplink sync codes (SYNC1 sequences) used by the UEs for UL synchronisation have a well known association to the P-RACHs, as broadcast by the BCH.

On the P-RACH, both power control and uplink synchronisation control is used.

#### 1.28Mcps functionality for UTRA TDD Physical Layer 50

The burst type used on the P-RACH is the same as for a traffic channel.

#### [Explanation difference:]

In low chip rate TDD option the random access procedure has two-step approach. The PRACH uses the close loop power control algorithm which is similar with the traffic channel.

In high chip rate TDD option the PRACH uses open loop power control. The details of the employed open loop power control algorithm may be different from the corresponding algorithm on other channels.

In low chip rate TDD option the burst type used on the P-RACH is the same as for a traffic channel while in high chip rate TDD option the burst type of the PRACH is a little different from the traffic channel.

### 7.3.2.4 The Uplink Shared Channel (USCH)

'Common with the high chip rate TDD mode'

### 7.3.2.5 The Downlink Shared Channel (DSCH)

### Figure B.2: Example for a multiframe structure for S-CCPCHs that is repeated every 72th frame, I,j=1? 16 (144 sub-frame)

The two codes at SF 16 which define the two P-(S)CCPCHs, are jointly used to deliver the same higher layer message! this means that it not possible to send contemporarily two different messages (e.g. BCH and PCH) onto the two different codes of the P-(S)CCPCH

# 8 Multiplexing and channel coding

# 8.1 Transport channel coding/multiplexing

# 8.1.1 Error detection

'Common with the high chip rate TDD mode'

### 8.1.2 Transport block concatenation and code block segmentation

'Common with the high chip rate TDD mode'

# 8.1.3 Channel coding

[Description:]

Usage of coding scheme and coding rate for the different types of TrCH is shown in table 1. In low chip rate TDD option, the coding scheme and coding rate of most type of TrCH are common with the high chip rate TDD.. Only BCH/PCH is a little different, it is mapped onto two code channels of the DL time slot. Rate 1/3 Convolutional coding is used for BCH and PCH.

[Rational:]

Usage of coding scheme and coding rate for the different types of TrCH is shown in table below. In low chip rate TDD option, BCH/PCH is mapped onto two physical channels of the DL time slot. If the usage of coding scheme and coding rate is 1/2 Convolutional coding, repeating as rate matching would be needed. So, it is used 1/3 Conv. coding as the coding scheme, this will lead to a better performance.

#### Table: Usage of channel coding scheme and coding rate

Type of TrCH	Coding scheme	Coding rate
BCH, PCH	Convolutional coding	1/3
RACH	Convolutional coding	1/2
		1/3, 1/2
DCH, DSCH, FACH, USCH	Turbo coding	1/3
	No coding	

The coding scheme and coding rate of other TrCH are common with high chip rate TDD and the following subclauses can be mentioned as "common with high rate TDD":

- 8.1.3.1 Convolutional Coding
- 8.1.3.2 Turbo coding
- 8.1.3.2.1 Turbo coder
- 8.1.3.2.2 Trellis termination in turbo code
- 8.1.3.2.3 Turbo code internal interleaver

### [Explanation difference:]

In high chip rate option, the coding scheme and coding rate of BCH/PCH is 1/2 Conv. coding. While in the low chip rate option, it is used 1/3 Conv. coding as the coding scheme and coding rate of BCH and PCH in low chip rate TDD option.

### 8.1.4 Radio frame size equalisation

'Common with the high chip rate TDD mode'

### 8.1.5 1st interleaving

'Common with the high chip rate TDD mode'

### 8.1.6 Radio frame segmentation

'Common with the high chip rate TDD mode'

# 8.1.7 Sub-frame segmentation

#### [Description:]

In the low chip rate option the radio frame which has a duration of 10 ms is subdivided into 2 subframes of 5ms each. The basic operated unit is a subframe. The bit streams in CCTrCH are mapped onto code channels of time slots in subframes. So, in low chip rate TDD option, it is needed to add the subframe segmentation unit between 2<sup>nd</sup> interleaving unit and physical channel mapping unit.

#### [Rational:]

In low chip rate option the radio frame which has a duration of 10 ms is subdivided into 2 subframes of 5ms each. The basic operated unit is a subframe. The bit streams in CCTrCH are mapped onto code channels of time slots in subframes. So, in low chip rate TDD option, it is needed to add subframe segmentation unit between 2<sup>nd</sup> interleaving unit and physical channel mapping unit. The operation of rate-matching guarantees that the bit streams is a even number and can be subdivided into 2 subframes. The transport channel multiplexing structure for uplink and downlink is shown in figure below.

The input bit sequence is denoted by  $x_{i1}, x_{i2}, x_{i3}$ , where *i* is the TrCH number and  $X_i$  is the number

bits. The two output bit sequences per radio frame are denoted by  $y_{i,n_i1}, y_{i,n_i2}, y_{i,n_i3}$ ?,  $y_{i,n_iY_i}$  where  $n_i$  is the subframe number in current radio frame and  $Y_i$  is the number of bits per radio frame for TrCH *i*. The output sequences are defined as follows:

 $y_{i,n,k} = x_{i,n,n,2,1,2,K}$ ,  $n_i = 1$  or 2,  $k = 1...Y_i$ 

where

 $Y_i = (X_i / 2)$  is the number of bits per subframe,

 $x_{ik}$  is the k<sup>th</sup> bit of the input bit sequence and

 $y_{ink}$  is the k<sup>th</sup> bit of the output bit sequence corresponding to the n<sup>th</sup> subframe

The input bit sequence to the radio frame segmentation is denoted by  $v_{(t)1}, v_{(t)2}, ..., v_{(t)U_{(t)}}, x_{ik} = v_{(t)k}$  and  $X_i = U_{(t)}$ .

The output bit sequence corresponding subframe  $n_i$  is denoted by  $g_{p1}, g_{p2}, ?$ ,  $g_{pU_p}$ , where p is the PhCH number and  $U_p$  is the number of bits in one subframe for the respective PhCH. Hence,  $g_{pk}$  ?  $y_{i,n,k}$  and  $U_p = Y_i$ .

#### Figure : Transport channel multiplexing structure for uplink and downlink

[Explanation difference:]

In low chip rate option the radio frame which has a duration of 10 ms is subdivided into 2 subframes of 5ms each. The bit streams in CCTrCH are mapped onto code channels of time slots in subframes. So, in low chip rate TDD option, it is needed to add subframe segmentation unit between 2<sup>d</sup> interleaving unit and physical channel mapping unit. While in high chip rate TDD option it is not included.

### 8.1.8 Rate matching

'Common with the high chip rate TDD mode'

# 8.1.9 TrCH multiplexing

'Common with the high chip rate TDD mode'

### 8.1.10 Physical channel segmentation

'Common with the high chip rate TDD mode'

# 8.1.11 2nd interleaving

'Common with the high chip rate TDD mode'

### 8.1.11.1 Frame related 2nd interleaving

8.1.11.2 Timeslot related 2<sup>nd</sup> interleaving

### 8.1.12 Physical channel mapping

#### [Description:]

In the low chip rate option the radio frame which has a duration of 10 ms is subdivided into 2 subframes of 5ms each. The basic operated unit is a subframe. So the bit streams from the subframe segmentation unit are mapped onto code channels of time slots in subframes in the low chip rate option.

### [Rational:]

In the low chip rate option the radio frame which has a duration of 10 ms is subdivided into 2 subframes of 5ms each. The basic operated unit is a subframe. So the bit streams from the subframe segmentation unit are mapped onto code channels of time slots in subframes in the low chip rate option.

The PhCH for both uplink and downlink is defined in subclause 7.2. The bits after physical channel mapping are denoted by  $w_{p1}, w_{p2}, ?$ ,  $w_{pU_p}$ , where *p* is the PhCH number and  $U_p$  is the number of bits in one subframe for the respective PhCH. The bits  $w_{pk}$  are mapped to the PhCHs so that the bits for each PhCH are transmitted over the air in ascending order with respect to *k*.

The mapping of the bits  $g_{p1}$ ,  $g_{p2}$ ,?,  $g_{pU_p}$  is performed like block interleaving, writing the bits into columns, but a PhCH with an odd number is filled in forward order, were as a PhCH with an even number is filled in reverse order.

The mapping scheme, as described in the following subclause, shall be applied individually for each timeslot *t* used in the current subframe. Therefore, the bits  $g_{p1}, g_{p2}$ ,?,  $g_{pU_p}$  are assigned to the bits of the physical

channels  $w_{t1,1...U_{t1}}, w_{t2,1...U_{t2}}, ..., w_{tP_t,1...U_{tP_t}}$  in each timeslot.

In uplink there are at most two codes allocated (P?2). If there is only one code, the same mapping as for downlink is applied. Denote SF1 and SF2 the spreading factors used for code 1 and 2, respectively. For the number of consecutive bits to assign per code  $b_k$  the following rule is applied:

```
if
```

```
SF1 >= SF2 then bs_1 = 1; bs_2 = SF1/SF2;
```

else

```
SF2 > SF1 then bs_1 = SF2/SF1; bs_2 = 1;
```

end if

In the downlink case bs<sub>p</sub> is 1 for all physical channels.

8.1.12.1 Mapping scheme

Notation used in this subclause:

 $P_t$ : number of physical channels for timeslot t,  $P_t = 1..2$  for uplink;  $P_t = 1...16$  for downlink

 $U_{tp}$ : capacity in bits for the physical channel p in timeslot t

 $U_t$ : total number of bits to be assigned for timeslot t

bs<sub>p</sub>: number of consecutive bits to assign per code

for downlink all  $bs_p = 1$ 

for uplink if SF1 >= SF2 then  $bs_1 = 1$ ;  $bs_2 = SF1/SF2$ ;

if SF2 > SF1 then  $bs_1 = SF2/SF1$ ;  $bs_2 = 1$ ;

fb<sub>p</sub>: number of already written bits for each code

pos: intermediate calculation variable

for p=1 to  $P_t$ -- reset number of already written bits for every physical channel  $fb_p = 0$ end for p = 1 -- start with PhCH #1 for k=1 to  $U_t$ do while (fb<sub>p</sub> ==  $U_{tp}$ ) -- physical channel filled up already ?  $p = ((p + 1) \mod (P_t + 1)) + 1;$ end do if (p mod 2) == 0  $pos = U_{tp} - fb_p$ -- reverse order else  $pos = fb_p + 1$ -- forward order endif  $W_{\text{tp.pos}} = g_{\text{t.k}}$ -- assignment  $fb_p = fb_p + 1$ -- Increment number of already written bits

if  $(fb_p \mod bs_p) == 0$  -- Conditional change to the next physical channel

 $p = ((p + 1) \mod (P_t + 1)) + 1;$ 

end if

end for

[Explanation difference:]

In the high chip rate TDD option, the bit streams from the 2<sup>nd</sup> interleaving unit are mapped onto code channels of timeslots in radio frames. While in the low chip rate option the radio frame which has a duration of 10 ms is subdivided into 2 subframes of 5ms each. The basic operated unit is a subframe. So the bit streams from the subframe segmentation unit are mapped onto code channels of time slots in subframes in the low chip rate option.

# 8.1.13 Multiplexing of different transport channels onto one CCTrCH, and mapping of one CCTrCH onto physical channels

'Common with the high chip rate TDD mode'

- 8.1.13.1 Allowed CCTrCH combinations for one UE
- 8.1.13.1.1 Allowed CCTrCH combinations on the uplink
- 8.1.13.1.2 Allowed CCTrCH combinations on the downlink

# 8.1.14 Transport format detection

'Common with the high chip rate TDD mode'

# 8.2 Coding for layer 1 control

# 8.2.1 Coding of transport format combination indicator (TFCI)

### [Description:]

Encoding of the TFCI bits depends on the number of them and the mode of modulation applied. When the modulation of QPSK is deployed, encoding of the TFCI bits is the same as it in the high chip rate option. When the modulation of 8PSK is applied, the encoding of the TFCI bits is a little different from it in high chip rate option.

### [Rationale:]

Encoding of the TFCI bits depends on the number of them and the mode of modulation applied. When the modulation of QPSK is deployed, encoding of the TFCI bits is the same as it in the high chip rate option. That is to say, if there are 6-10 bits of TFCI, the TFCI bits are encoded using a (32,10) sub-code of the second order Reed-Muller code. If the number of TFCI bits is in the range 3 to 5, the TFCI bits are encoded using a (16, 5) biorthogonal (or first order Reed-Muller) code. If the number of TFCI bits is 1 or 2, then repetition will be used for coding. In this case each bit is repeated to a total of 4 times giving 4-bit transmission ( $N_{TFCI}$ =4) for a single TFCI bits applied in low chip rate option. In this case of 8PSK service, the odd bits of the encoded TFCI bits from the TFCI coder are repeated (e.g. the input is b0, b1, b2, b3, b4... the output will be b0, b1, b1, b2, b3, b3, b4...). Thus the amount of encoded bits of TFCI in this case will be 48, 24, 12, 6 respectively for the 6-10, 3-5, 2, 1 TFCI bits. The same TFCI lengths like in WB-TDD are supported (0, 4, 8, 16, 32).

Other TFCI coding scheme for 8PSK is also considered.

[Explanation difference:]

In high chip rate option, encoding of the TFCI bits depends on the number of them. 1-10 bits of TFCI are supported. Thus, the amount of encoded bits of TFCI is 32, 16, 8, 4 respectively for the 6-10, 3-5, 2, 1 TFCI bits.

In the low chip rate option, encoding of the TFCI bits depends on the number of them and the mode of modulation applied. When the modulation of QPSK is deployed, encoding of the TFCI bits is the same as it in the high chip rate option. In this case of 8PSK service, the odd bits of the encoded TFCI bits from the TFCI coder are repeated, thus the amount of encoded bits of TFCI in this case will be 48, 24, 12, 6 respectively for the 6-10, 3-5, 2, 1 of TFCI bits. The repetition of TFCI odd bits is necessary to guarantee the same number of symbols.

Note: Details of the TFCI coding with 8PSK are for further study and proposals are under consideration.

# 8.2.2 Coding of Synchronisation Shift

#### [Description:]

The SS command, one kind of L1 control signals, is an identifier sent in downlink, to instruct a timing adjustment each M frames. The length of the SS command is 1 symbol.

#### [Rational:]

The SS command is sent in every sub-frame (in case allocated). The command may be updated only after every M sub-frames. I. The coding of the SS command is shown in table below. M (1-8) and k (1-8) can be adjusted during call setup or readjusted during the call by higher layer.

SS Bits	Meaning
11	Increase timing advance by k/8 Tc
00	Decrease timing advance by k/8 Tc

Table: Coding of the SS

\* Note: other methods like e.g. definition of 'do nothing' are under consideration

In case of 8PSK service, the numbers of the SS bits is3. The specific coding of SS for the case of 8PSK service is shown in table below.

SS Bits	Meaning
111	Increase timing advance k/8 Tc
001	Decrease timing advance k/8 Tc

\* Note: other methods like e.g. definition of 'do nothing' are under consideration

[Explanation difference:]

In high chip rate TDD option, SS information is not transmitted as L1 signal on each frame. Because of uplink synchronisation in the low chip rate TDD option, SS information is transmitted, as one of L1 signals, once per 5ms subframe.

The SS command is an identifier sent in downlink, to instruct a timing adjustment each M frames. The length of the SS command is 1 symbol. The SS bits "11" mean increasing timing advance k/8 Tc and "00" mean decreasing the timing advance by k/8 T<sub>c</sub>. The modulation of 8PSK is applied, e.g. in case of 2Mbps service. In this case, the numbers of the SS bits is 3. The specific coding of SS for the case of 8PSK service is shown in table above.

# 8.2.3 Coding of Transmit Power Control (TPC)

#### [Description:]

The TPC command, one kind of L1 control signals, is an identifier sent both in up- and downlink, to instruct a power level adjustment which is increase or decrease. The coding of the TPC command is shown.

[Rationale:]

The TPC command is an identifier sent both in up- and downlink, to instruct a power level adjustment which is increase or decrease. The length of the TPC command is one symbol. The coding of the TPC command is shown in table 1.

TPC	TPC Bits	Meaning
'Up'	11	Increase Tx Power
'Down'	00	Decrease Tx Power

Table: Coding of the TPC

\* Note: other methods like e.g. definition of 'do nothing' are under consideration

When 8PSK modulation is applied, the length of the coded TPC command remains one symbol and therefore the number of TPC Bits is 3. The specific coding of TPC for the case of 2Mbps service is shown in table 2.

Table: Coding of the TPC (Special for 8PSK)

TPC	TPC Bits	Meaning
'Up'	111	Increase TX power
'Down'	001	Decrease TX power

\* Note1: other methods like e.g. definition of 'do nothing' is under consideration

\* Note2: the TPC coding for 8PSK refer to 9.1.2

### [Explanation difference:]

In high chip rate option, the TPC command is sent in uplink transmission only, to instruct the NodeB whether Tx power has to be increased or decreased. The length of the TPC command is one symbol.

In the low chip rate option, the TPC command is an identifier sent both in up- and downlink, to instruct a power level adjustment which is increase or decrease. When 8PSK modulation is applied the length of the coded TPC command remains one symbol and therefore the number of TPC Bits is 3. The specific coding of TPC for the case of 8PSK is shown in table above. Other methods like e.g. to define the command of 'do nothing' is under consideration.

# 8.2.4 Coding of the Paging Indicator

Common with the high chip rate TDD option

# 9 Spreading and Modulation

# 9.1 Data modulation

[Description:]

This document is described the difference of modulation and spreading in low chip rate TDD. The main difference is the mapping of bits onto signal point constellation, synchronization codes and code Allocation.

[Rational:]

# 9.1.2 Mapping of bits onto signal point constellation

### 9.1.2.1 QPSK modulation

'Common with high chip rate TDD'

### 9.1.2.2 8PSK modulation

The data modulation is performed to the bits from the output of the physical channel mapping procedure for 8PSK service 3 consecutive binary bits to a complex valued data symbol. Each user burst has two data carrying parts, termed data blocks:

$$\underline{\mathbf{d}}^{(k,i)}?(\underline{d}_{1}^{(k,i)},\underline{d}_{2}^{(k,i)},...,\underline{d}_{N_{k}}^{(k,i)})^{\mathrm{T}} \ i=1,2; k=1,..., \mathrm{K}.$$
(1)

Nk is the number of symbols per data field for the user k. This number is linked to the spreading factor Qk.

Data block  $\underline{\mathbf{d}}^{(k,1)}$  is transmitted before the midamble and data block  $\underline{\mathbf{d}}^{(k,2)}$  after the midamble. Each of the  $N_k$  data symbols  $\underline{d}_n^{(k,i)}$ ; i=1, 2; k=1,...,K; n=1,...,N<sub>k</sub>; of equation 1 has the symbol duration  $T_s^{(k)}$ ?  $Q_k T_c$  as already given.

The data modulation is 8PSK, thus the data symbols  $\underline{d}_{n}^{(k,i)}$  are generated from 3 consecutive data bits from the output of the physical channel mapping procedure:

using the following mapping to complex symbols:

Consecutive binary bit pattern	complex symbol
$b_{l,n}^{(k,i)} b_{2,n}^{(k,i)} b_{3,n}^{(k,i)}$	$\frac{d}{n}^{(k,i)}_n$
000	Cos(11pi/8)+sin(11pi/8 )
001	Cos(9pi/8)+sin(9pi/8)
010	Cos(5pi/8)+sin(5pi/8)
011	Cos(7pi/8)+sin(7pi/8)j
100	Cos(13pi/8)+sin(13pi/8 )
101	Cos(15pi/8)+sin(15pi/8

	)
110	Cos(3pi/8)+sin(3pi/8)1
111	Cos(pi/8)+sin(pi/8)

The mapping corresponds to a 8PSK modulation of the interleaved and encoded data bits  $b_{l,n}^{(k,i)}$  of the table above and  $\underline{d}_{n}^{(k,i)}$  of equation 1.

The use of shifted 8PSK is under consideration.

### DwPTS code

The DwPTS is composed of 64 chips (4 symbols) of SYNC and 32 chips (2 symbols) of guard period as shown

<sup>31.5</sup> symbols (393.75 ?s)

in Figure below. SYNC code is not scrambled.

#### Figure : The frame structure around DwPTS

The phase of the whole DwPTS is used to signal the P-CCPCH multi-frame. As QPSK is used for the modulation of the DwPTS, the phases 45, 135, 225, 315° is used to signal. Indication of starting point of the phase quadruple and the position of the BCH is realised by means of direct signalling. In this method the phase of 45° is reserved for the beginning of each phase quadruple. For the other sub-frames of the phase quadruple, the phase 135°, 225° and 315° are used only to detect the position of the BCH as shown Table 1.

The sequence of the phases is chosen, that the position of the BCH can also be detected by using differential demodulation of the consecutive phases of the DwPTS.

Phase quadruple	# 225	(SFN/2) mod 8
45, 225, 225, 225	3	0 (the BCH should be here)
45, 135, 135, 225	1	1
45, 135, 225, 135	1	2
45, 315, 225, 315	1	3
45, 225, 135, 315	1	4
45, 225, 315, 315	1	5
45, 225, 225, 135	2	6
45, 225, 225, 315	2	7
Others	-	Error

Table Sequence for the phase modulation for the DwPTS

There should be 32 different SYNC codes (see Table A) for the whole system. That the (SFN/2) mod 8= 0 is always used for BCH. Other position can also be configured to transmit the BCH.

UpPTS code

Synchronisation sequences for the UpPTS (SYNC1)

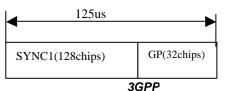

SYNC1 code is not scrambled.

The time slot is composed of 128chips of SYNC1 and 32chips of GP as shown in Figure 2.

There should be 256 different SYNC1 codes (see Table B) for the whole system.

#### Figure Burst structure of UpPTS

The possible restriction to the network planning from parameter grouping is to be verified.

#### [Explanation difference:]

For low chip rate have different frame structure. It has the special time slot DwPTS and UpPTS to estimate the UL-synchronization and Cell search. So the Sync and Sync1 code is needed in low chip rate TDD.

# 10 Physical layer procedures

# 10.1 Transmitter Power Control

#### [Description:]

The basic purpose of power control is to limit the interference level within the system thus reducing the intercell interference level and to reduce the power consumption in the UE.

[Rationale:]

**General Parameters** 

The main characteristics of power control are summarized in the following table.

Table: Transmit Power Control characteristics

	Uplink	Downlink
Power control rate	Variable	Variable
	Closed loop: 0-200 cycles/sec.	closed loop: 0-200 cycles/sec.
	Open loop: (about 200us – 3575us delay )	
Step size	1,2,3 dB (closed loop)	1,2,3 dB (closed loop)
Remarks	All figures are without processing and measurement times	within one timeslot the powers of all active codes may be balanced to within a range of [20] dB

Note:

All codes within one timeslot allocated to the same CCTrCH use the same transmission power in case they have the same Spreading Factor. In case of different spreading factors in the uplink for the same CCtrCH are used , the power levels of the parallel codes portion are under further study.

### 10.1.2 Uplink Control

Open loop power control for the UpPTS

The transmit power level by a UE on the UpPTS shall be calculated based on the following equation:

 $P_{UPTS} = L_{P-CCPCH} + PRX_{UPTS,des}$ 

where, P<sub>UpPTS</sub>: transmit power level in dBm,

LP-CCPCH: measured path loss in dB (P-CCPCH reference transmit power level is broadcast on BCH),

PRX<sub>UpPTS,des</sub>: desired RX power level at cell's receiver in dBm, which is broadcast on BCH.

The interference power on the UpPTS ( $I_{UpPTS}$ ) measured by the Node B is reported to the RNC on a regular basis to allow the RNC to make a decision for new control parameters.

The network signals (on BCH) a power increment that is applied only for the access procedure. At each new transmission of a SYNC1 burst during the access procedure, the transmit power level can be increased by this power increment.

#### 10.1.2.2 Common Physical Channel

In low chip rate TDD option system, the F-PACH brings the answer to the SYNC1 burst of the UE. The answer, a one burst long message, shall bring besides the acknowledgment to the received SYNC1 burst, the timing and power level indications to prepare the transmission of the RACH burst.

The transmit power level on the PRACH is calculated by the following equation:

```
P<sub>PRACH</sub>= L<sub>P-CCPCH</sub> + PRX<sub>PRACH,des</sub>
```

Where, P<sub>PRACH</sub> is the UE transmit power level on the PRACH;

PRX<sub>PRACH,des</sub> is the desired receive power level on the PRACH, as signalled by the network on the F-PACH

The network computes the  $PRX_{PRACH,des}$  by measuring the interference on the PRACH timeslot which has to be averaged over an configurable (by O&M) number of frames (N).

#### 10.1.2.3 Dedicated Physical Channel

The closed loop power control makes uses of layer 1 symbol in the DPCH. The power control step can take the values 1,2,3 dB within the overall dynamic range 80dB. The initial transmission power of the uplink Dedicated Physical Channel is signalled by the UTRAN.

Closed-loop TPC is based on SIR, and the TPC processing procedures are described in this section. During this power control process, the node B periodically makes a comparison between the received SIR measured value and the target SIR value. When the measured value is higher than the target SIR value, TPC command ='down'. When this is lower than the target SIR value, TPC command = 'up'. At the UE, soft decision on the TPC bits is performed, and when it is judged as 'down', the mobile transmit power shall be reduced by one power control step, whereas if it is judged as 'up', the mobile transmit power shall be raised by one power control step. A higher layer outer loop adjusts the target SIR. This scheme allows quality based power control.

When the TPC bit cannot be received due to out-of-synchronisation, the transmission power value shall be kept at a constant value. When SIR measurement cannot be performed for being out-of-synchronisation, the TPC command shall always be set to = 'up' during the period of being out-of-synchronisation.

### 10.1.3 Downlink Control

#### 10.1.3.1 Common Physical Channel

The power of the P-CCPCH

The primary CCPCH transmit power is set by high layer signalling and can be changed based on network determination. The reference power of P-CCPCH is signalled on the BCCH on a periodic basis.

The power value for the F-PACH is set by the network.

The power of the S-CCPCH (for FACH)

It is set by the network and can take into account both the received power level on the PRACH from the addressed UE and the transmit power level as signalled by the UE.

The power of the S-CCPCH(for PCH)

This condition is the same as P-CCPCH.

#### 10.1.3.2 Dedicated Physical Channel

The initial transmission power of the downlink Dedicated Physical Channel is set by the network until the first UL DPCH arrives. After the initial transmission, the node B transits into SIR-based closed-loop TPC.

The measurement of received SIR shall be carried out periodically at the UE. When the measured value is higher than the target SIR value, TPC command ='down'. When this is lower than the target SIR value, TPC command = 'up'. At the Node B, soft decision on the TPC bits is performed, and when it is judged as 'down', the transmission power shall be reduced by one power control step, whereas if judged as 'up', the transmission power shall be raised by one power control step.

When the TPC bit cannot be received due to out-of-synchronisation, the transmission power value shall be kept at a constant value.

When SIR measurement cannot be performed due to out-of-synchronisation, the TPC command shall always be = 'up' during the period of being out-of-synchronisation.

[Explanation difference:]

In low chip rate TDD option, for uplink , the power control update of PRACH can be calculated according to the received power of UpPTS. The power control of the DPCH is closed loop transmitter power control . Closed loop power control in uplink is used because of beamforming. Open loop power control is under consideration if there is no beamforming . For the downlink the transmit power control adjustment of the S-CCPCH(for FACH) can be calculated according the transmit power level signaled in the RACH .

In high chip rate TDD option, for uplink, the power controls of the PRACH and DPCH are open loop transmitter power control. For downlink, the initial transmission power of DPCH is set by the network.

Operation of multiple CCtrCH is under studying.

# 10.2 Timing Advance

## 10.2.1 With UL Synchronization

[Description:]

This section described the detail description on the UL synchronization including the establishment of UL synchronization and maintenance of the UL synchronization.

[Rationale:]

#### 10.2.1.1 The establishment of uplink synchronization

#### 10.2.1.1.1 Preparation of uplink synchronization (downlink synchronization)

When a UE is powered on, it first needs to establish the downlink synchronisation with the cell as describe in paper about cell search procedure. Only after the UE can establish and maintain the downlink synchronisation, it can start the uplink synchronisation procedure.

#### 10.2.1.1.2 Establishment uplink synchronization

Although the UE can receive the downlink synchronization signal from the Node B, the distance to Node B is still uncertain which would lead unsynchronised uplink transmission. Therefore, the first transmission in uplink direction is performed in a special time-slot UpPTS to reduce interference in traffic time-slots.

The timing used for the SYNC1 burst are set e.g. according to the received power level of DwPTS and/or P-CCPCH.

At the detection of the SYNC1 sequence in the searching window, the Node B will evaluate the received power levels and timing, and reply by sending the adjustment information to UE to modify its timing and power level for next transmission and for establishment of the uplink synchronisation procedure. Within the next 4 sub-frames, the Node B will send the adjustment information to the UE (in a single subframe message in theFPACH) The uplink synchronisation procedure, normally used for a random access to the system, can also be used for the re-establishment of the uplink synchronisation when uplink is out of synchronisation.

#### 10.2.1.2. Maintenance of uplink synchronisation

For the maintenance of the uplink synchronization, the midamble field of each uplink burst can be used.

In each uplink time slot the midamble in each UE is different. The Node B can estimate the power level and timing shift by measuring the midamble field of each UE in the same time slot. Then, in the next available downlink time slot, the Node B will signal the Synchronisation Shift (SS) and the Power Control (PC) commands to enable the UE to properly adjust respectively its Tx timing and Tx power level.

These procedures guarantee the reliability of the uplink synchronisation. The uplink synchronization can be checked once per TDD sub-frame. The step size in uplink synchronization is configurable and re-configurable and can be adapted from 1/8 chip to 1 chip duration. The following updates for UL synchronization are possible: 1 step up; 1 step down; no update.

#### [Explanation difference:]

For high chip rate option, uplink synchronisation is mentioned in 4.3 of TS25.224. But the implementation method is a little different with the low chip rate option. For low chip rate option, the establishment of the UL synchronization is done by using the UpPTS and theFPACH.

It allocates a unique time slot UpPTS for UE to establish uplink synchronisation in the access procedure. The benefit of this method is when the UE wants to do random access, the P-RACH will have minimum interference to other traffic channel. Vice versa, it will also reduce the interference from traffic channels to P-RACH.

# 10.3 Synchronisation and Cell Search Procedures

### 10.3.1 Cell Search

#### [Description:]

In this section, a 4step cell search procedure for low chip rate TDD option is described which is a slightly different with the current 3 step cell search procedure for high chip rate TDD option. [Rational:]

During the initial cell search, the UE searches for a cell. It then determines the DwPTS synchronization, scrambling and basic midamble code identification, control multi-frame synchronisation and then reads the contents in BCH. This initial cell search is carried out in 4 steps:

#### Step 1: Search for DwPTS

During the first step of the initial cell search procedure, the UE uses the SYNC (in DwPTS) to acquire DwPTS synchronization to a cell. This is typically done with one or more matched fitters (or any similar device) matched to the received SYNC which is chosen from PN sequences set. A single or more matched filter (or any similar device) is used for this purpose. During this procedure, the UE needs to identify which of the 32 possible SYNC sequences is used.

Step 2: Scrambling and basic midamble code identification

During the second step of the initial cell search procedure, the UE receives the midamble of the P-CCPCH.The P-CCPCH is followed by the DwPTS. In the current low chip rate TDD option each DwPTS code corresponds to a group of 4 different basic midamble code. Therefore there are total 128 midamble codes and these codes are not overlapping with each other. Basic midamble code number divided by 4 gives the SYNC code number. Since the SYNC and the group of basic midamble codes of the P-CCPCH are related one by one (that is, once the SYNC is detected, the 4 midamble codes can be determined), the UE knows which 4 basic midamble codes is used. Then the UE can determine the used basic midamble code using a try and error technique. The same basic midamble code will be used throughout the frame. As each basic midamble code is associated with a scrambling code, the scrambling code is also known by that time. According to the result of the search for the right midamble code, UE may go to next step or go back to step 1.Step 3: Control multi-frame synchronisation

During the third step of the initial cell search procedure, the UE searches for the head of multi-frame indicated by QPSK phase modulation of the DwPTS with respect to the P-CCPCH midamble. The control multi-frame is positioned by a sequence of QPSK symbols modulated on the DwPTS. [n]consecutive DwPTS are sufficient for detecting the current position in the control multi-frame. To ensure correct decisions, an additional bit coded together with a BCH block, allows the UE to know the BCH interleaving block in P-CCPCH. According to the result of the control multi-frame synchronisation for the right midamble code, UE may go to next step or go back to step 2.

#### Step 4: Read the BCH

The (complete) broadcast information of the found cell in one or several BCHs is read. According to the result the UE may move back to previous steps or the initial cell search is finished.

#### [Explanation difference:]

The initial cell search procedure is optimized considering the frame structure that is needed to enable UL synchronization and other specific features and properties for low chip rate option .

For high chip rate option , the three steps are : slot synchronisation, frame synchronisation and code-group identification, scrambling code identification.

For low chip rate option , the four steps are : search for DwPTS , scrambling and basic midamble code identification, control multi-frame synchronisation and the read of BCH information.

# 10.4 Discontinuous transmission (DTX) of Radio Frames

'Common with the high chip rate TDD mode'

#### [Description:]

The different downlink transmit diversity schemes for different channel has been considered in low chip rate TDD option.

[Rationale:]

# 10.5 Downlink Transmit Diversity

### 10.5.1 Transmit Diversity for DPCH

'Common with the high chip rate TDD'

### 10.5.2 Transmit Diversity for SCH

The SCH function in high chip rate TDD has been achieved by DwPTS in low chip rate TDD and transmit diversity schemes for the DwPTS in low chip rate TDD is common with that for SCH in high chip rate TDD.

# 10.5.3 Transmit Diversity for P-CCPCH

Transmit diversity for P-CCPCH as in the high chip rate option (i.e., Block STTD) is not supported in low chip rate TDD.

#### [Explanation difference:]

If both the uplink and downlink physical channels are work under the synchronization mode and if "smart antenna" method is used, the interference on P-CCPCH is thought to be very little in low chip rate TDD option. As a result, "Tx diversity" has not been considered currently to be applied in low chip rate TDD. As this may not hold in all cases, the Block STTD applied for P-CCPCH is to be studied.

### 10.5.4 Transmit diversity for FPACH

The same scheme as for the DPCH can be used for the FPACH.

# 10.6 Random Access Procedure

#### [Description:]

The random access procedure and the collision problems for low chip rate option are described here. It include the preparation of random access, the random access procedure and the procedure for random access collision.

Note:

In this paper, the FPACH is just a physical channel used to carry one burst message responding to SYNC1 during random access procedure. There is no mapping relationship between FACH and FPACH. The FPACH here is a little like the AICH in FDD.

[Rationale:]

# 10.6.1 Preparation of random access

When the UE is in Idle mode, it will keep the downlink synchronisation and read the cell broadcast information. From the used DwPTS, the UE will get the code set of 8 SYNC1 codes (signatures) assigned to UpPTS physical channel for random access. There are total 256 different SYNC1 sequences. SYNC1 sequences number divided by 8 gives the DwPTS sequences number. From the cell broadcast information, the UE will get to know the used SYNC1 sequences within the code set to be used; the description (codes, spreading factor, midambles, time slots) of the P-RACH channels, the description (codes, spreading factor, midambles, time slots) of the FPACH channels, and other information (if needed ) related to random access.

In the BCH it is described what SYNC1 sequences are associated with what FPACH resources; what FPACHs are associated with what PRACH resources and what P-RACH resources are associated with what (P/S-)CCPCH (carrying the FACH logical channel) resources.

Thus, when sending a SYNC1 sequence, the UE knows which FPACH resources, P-RACH resources and CCPCH resources will be used for the access.

## 10.6.2 Random access procedures

The SYNC1 sequence in UpPTS following the guard time slot is used only for uplink synchronisation. The UE randomly selects one of the 1-8 possible signatures of the cell it wants to access to and sends it on the UpPTS physical channel.

Then the UE determines the timing and the Tx power level (open loop procedure) for the UpPTS and transmits the selected signature on the UpPTS.

Once the Node B detects the UpPTS transmission from an UE, the arrival time and the received power are known. The Node B determines the Tx power update and timing adjustment and sends them to the UE within the next four frames through the FPACH (in a single burst/sub-frame message). Note that the FPACH also contains the signature reference and the relative frame number (number of frames passed after the reception of the acknowledged signature) for cross check with the UE.

Once the UE receives the above mentioned control signalling from the chosen FPACH (i.e. the FPACH which is associated to the selected signature), its UpPTS sequence has been accepted by the Node B. Then the UE will adjust its timing and power level and send the RACH (also as a single burst/sub-frame message) on the P-RACH channel corresponding to the FPACH exactly two frames later. In this step, the RACH sent to Node B by UE will have high synchronisation precision.

After that, the UE will receive a response from the network from the CCPCH associated to the P-RACH (by the FACH logical channel) indicating whether the UE random access has been accepted or not. In case it has been accepted the further signalling for establishing the link will take place on UL and DL dedicated channels assigned by the network through the FACH.

The UE can transmit a second UpPTS and wait for the response from the FPACH for a further power and SS update before transmitting on the assigned resources.

Note: Details of the random access procedure including the FPACH coding are for further study and proposals are under consideration.

# 10.6.3 Random access collision

When a collision is very likely or in bad propagation environment, the Node B does not transmit the FPACH or cannot receive the SYNC1. In this case, the UE will not get any response from the Node B. Thus the UE will have to adjust its Tx time and Tx power level based on a new measurement and send a SYNC1 again after a random delay.

Note that at each (re-)transmission, the SYNC1 burst will be randomly selected again by the UE.

Due to the two-step approach a collision most likely happens on the UpPTS. The RACH RUs are virtually collision free. This two-step approach will guarantee that the RACH RUs can be handled with conventional traffic on the same UL time slots.

#### [Explanation difference:]

Different from the high chip rate option , the random access procedure of low chip rate option has two-step approach. The SYNC1 word is used to carry out uplink synchronisation and to resolve the access collision. This two-step procedure enables the RACH RUs to be handled with conventional traffic on the same UL time slots.

# 11 Physical layer measurements

All the sections of this chapter are marked as: 'Common with the high chip rate TDD mode'. The range/mapping values should be discussed in WG2/WG4.

# Annex A (informative): Monitoring GSM from low chip rate TDD: Calculation Results

#### [Description:]

This paper gives some general description about how to monitor GSM from the low chip rate TDD.

#### [Rationale:]

A.1 Low data rate traffic using 1 uplink and 1 downlink slot

NOTE: The section evaluates the time to acquire the FCCH if all idle slots are devoted to the tracking of a FCCH burst, meaning that no power measurements is done concurrently. The derived figures are better than those for GSM. The section does not derive though any conclusion. A conclusion may be that the use of the idle slots is a valid option. An alternative conclusion may be that this is the only mode to be used, removing hence the use of the slotted frames for low data traffic or the need for a dual receiver, if we were to considering the monitoring of GSM cells only, rather than GSM, TDD and FDD.

If a single synthesiser UE uses only one uplink and one downlink slot, e.g. for speech communication, the UE is not in transmit or receive state during 5 slots in each frame. According to the timeslot numbers allocated to the traffic, this period can be split into two continuous idle intervals A and B as shown in the figure below.

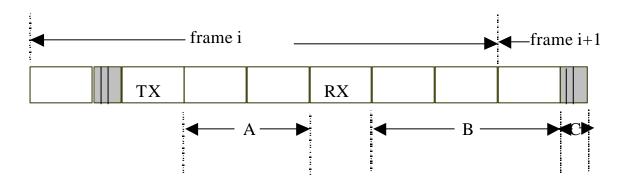

Figure A.1: Possible idle periods in a subframe with two occupied timeslots

A is defined as the number of idle slots between the Tx and Rx slots and B the number of idle slots between the Rx and Tx slots. It is clear that A+B=5 time slots and C is equal to the DwPTS+GP+UpPTS.

In the scope of low cost terminals, a [0.5] ms period is supposed to be required to perform a frequency jump from low chip rate TDD to GSM and vice versa. This lets possibly two free periods of A\*Ts-1 ms and B\*Ts+C-1 ms during which the mobile station can monitor GSM, Ts being the slot period.

Following table evaluates the average synchronisation time and maximum synchronisation time, where the announced synchronisation time corresponds to the time needed to find the FCCH. The FCCH is supposed to be perfectly detected which means that it is entirely present in the monitoring window. The FCCH being found the SCH location is unambiguously known from that point. All the 5 idle slots and the DwPTS+GP+UpPTS are assumed to be devoted to FCCH tracking and the UL traffic is supposed to occupy the time slot 1.

Table A.1: example- of average and maximum synchronisation time with two busy timeslots per frame and with 0.5 ms switching time

Downlink time				Maximum
slot number	free TS in	free TS in	synchronisation time	
	A	В	(ms)	time (ms)
0	5	0	83	231
2	0	5	75	186
3	1	4	98	232
4	2	3	185	558
5	3	2	288	656
6	4	1	110	371

(\*) All simulations have been performed with a random initial delay between GSM frames and low chip rate TDD subframes.

Each configuration of TS allocation described above allows a monitoring period sufficient to acquire synchronisation.

A.1.1 Higher data rate traffic using more than 1 uplink and/or 1 downlink TDD timeslot

The minimum idle time to detect a complete FCCH burst for all possible alignments between the GSM and the TDD frame structure (called 'guaranteed FCCH detection'), assuming that monitoring happens every TDD frame, can be calculated as follows ( $t_{FCCH}$  = one GSM slot):

$$t_{\min, guarante\ ed}$$
 ? 2 ?  $t_{synth}$  ?  $t_{FCCH}$  ?  $\frac{5 \, \text{ms}}{13}$  ? 2 ?  $t_{synth}$  ?  $\frac{25 \, \text{ms}}{26}$ 

- (e.g for  $t_{synth} = 0ms: 2$  low chip rate TDD **consecutive** idle timeslots needed, for  $t_{synth} = 0.3ms: 3$  slots (or 2 slots and the DwPTS+GP+UpPTS), for  $t_{synth} = 0.5ms: 3$  slots, for  $t_{synth} = 0.8ms: 4$  slots). Under this conditions the FCCH detection time can never exceed the time of 660ms.

- (For a more general consideration t<sub>synth</sub> may be considered as a sum of all delays before starting monitoring is possible).

- For detecting SCH instead of FCCH (for a parallel search) the same equation applies.
- In the equation before the dual synthesiser UE is included if the synthesiser switching time is 0ms.

Considering about the frame structure of the low chip rate TDD, there are total 7 timeslot in each frame that can be used as data traffic. If more than 1 uplink and/or 1 downlink TDD timeslot are used for data traffic, that means it will occupy at least 3 time slot, equal to 0.675\*3=2.205ms. And more time slots for traffic data means more switching point are needed to switch between the GSM and the low chip rate TDD. As it was mentioned above, each switching will take 0.5ms. As a result, the idle time left for monitoring the GSM will be very little. So monitoring GSM from low chip rate TDD under this situation will be considered in the future. It will need more carefully calculation and simulation.

For a synthesiser switching time of one or one half TDD timeslot the number of needed consecutive idle TDD timeslots is summarized in the table below:

Table A.2: Link between the synthesiser performance and the number of free consecutive TSs for guaranteed FCCH detection, needed for GSM monitoring

One-way switching time for the synthesiser	Number of free consecutive TDD timeslots needed in the frame for a guaranteed FCCH detection
1 TS (=864 chips)	4
0.5 TS (=432 chips)	3
0 (dual synthesiser)	2

#### [Explanation difference:]

Due to the different operating bandwidth and the different frame structure, some measurement method about how to monitor GSM are different between the high and low chip rate TDD.

# 12 Performance analysis of the low chip rate

#### Simulation assumptions

Note: Some of the assumptions may need further clarifications. Other simulations may also be needed to clarify some of the special features of the low chip rate TDD.

Calculation of the  $E_b/N_0$ 

Intercell interference is modeled as white Gaussian noise. In the following, bit error rates (BER) are given as a function of the average  $E_b/N_0$  (or as a function of average C/I) in dB ( $E_b$  is the energy per bit and  $N_0$  is the one-sided spectral noise density) with the intracell interference, i.e. the number K of active users per time slot as a parameter. The relation between the  $E_b/N_0$  and the carrier to interference ratio C/I, with C denoting the carrier power per CDMA code and with I denoting the intercell interference power, is given by

$$\frac{C}{I}?\frac{E_b}{N_0}?\frac{R_c \log_2 M}{B?Q?T_c}$$
(1.1)

with

 $R_{\rm c}$  the rate of the channel encoder (depends on the service),

- M the size of the data symbol alphabet (4),
- B the user bandwidth
- Q the number of chips per symbol (16) and
- $T_c$  the chip duration (0.24414 ?s).

The expression  $log_2M$  is the number of bits per data symbol and  $QxT_c/log_2M$  is the bit duration at the output of the encoder. One net information bit is transmitted in a duration of  $QxT_c/(R_cxlog_2M)$ . Therefore, (1.1) is equivalent to  $C/I = (E_b/T_b)/(N_0xB)$ , i.e.,  $C = E_b/T_b$  and  $I = N_0xB$  with  $T_b$  the duration of a net information bit. The carrier to interference ratio per user is K<sub>c</sub> times the carrier to interference ratio per CDMA code, with K<sub>c</sub> denoting the number of CDMA codes per time slot per user.

The  $E_b/N_0$  (as the C/I) is calculated at the antenna connector of the antenna elements.

#### Channel model

In case smart antennas are used the channel model is like the vehicular A model used for ITU and ETSI 30.03. The channel model has been adapted to the smart antenna environment such that the directions of arrival (DOA) for the multipaths are uniformly distributed.

#### Antenna array

Figure 1 shows the circular array used in smart antenna simulations. The circular array is suitable for omnidirectional cell design. Let the array be composed of N antenna elements, where the first (reference) antenna element is located at the position of (R, 0), and the k-th element is located at the location of  $(R \cos 2k?/N, R \sin 2k?/N)$  in circular array.

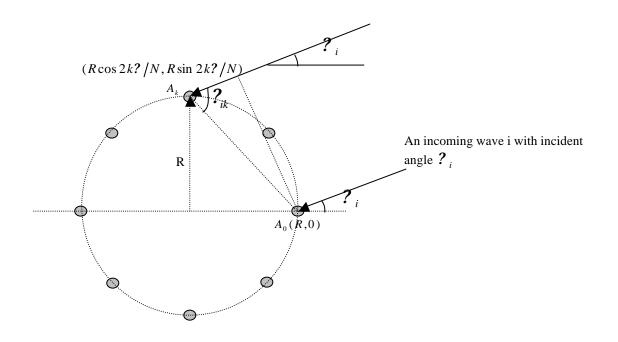

Figure . The geometric illustration for circular antenna array

Then, when an incoming wave i from the direction of  $?_i$ , for circular array, the differential optical distance  $(D_{ik})$  between the first and the k-th antenna element will be

 $D_{ik}$ ?  $R \cos?_{ik} [2(1? \cos 2k?/N)]^{1/2}$ 

where R is the radius of the circular array;

k ? 1,2,?, N ? 1;

N is the total number of antenna element.

The incident wave comes from the direction of  $?_i$  as shown in Figure 1, and

$$?_{ik}$$
?  $?_{i}$ ?  $?(1/2? k/N)$ 

Let's denote  $S_{ki}(n)$  as the Rx signal at the k-th antenna element from the i-th path of the

j -th UE ,then

$$S_{kj}(n)$$
? ?  $a_{ji}(n) \exp[? j(??_{ji}??_{kji})]$  for the *n*-th sampling

where,  $a_{ji}(n)$  is the amplitude of the *i*-th path from the *j*-th UE;

 $\boldsymbol{?}_{_{ji}}$  is the time delay of the *i*-th path from the *j*-th UE;

 $i_{kji}$  is the phase different between the k-th element and the reference element for the i-th path from the j-th UE:

 $?_{jik}$ ? 2?  $D_{jik}/?$ 

and  $D_{jik}$  is the differential optical distance between the first and the k-th antenna element for the i-th path from the j-th UE;

? is the angle frequency and ? is the wavelength.

Simulation results

Simulation for BCH

Simulation for 2Mbps

The simulations for the indoor environments in uplink are considered. The channel model is compatible with the one in UMTS 30.03. The main parameters are listed as following:

Parameters

Service: 2 Mbps service

Channel model: Indoor A

Channel coding: None

Modulation/Demodulation: 8PSK;

Power Control: Ideal power control

Frame structure: 5ms

Number of time slot: 5

Codes per time slot: 16

#### Simulation Results

The following table and figures in next pages present the simulation results for 2 Mbps service without channel coding considered.

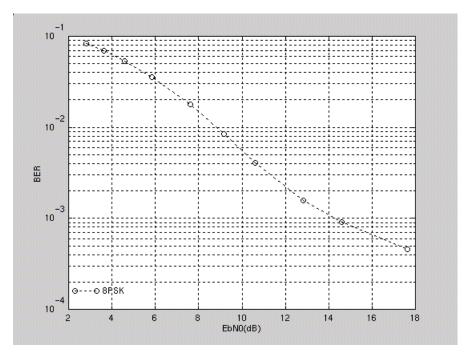

Figure : BER vs. EbNo for 2 Mbps service

(without coding using 8PSK modulation scheme)

# 13 Examples of service mapping

#### B.1 BCH

Note: Other means for BCH indication are under consideration.

Table B.1 Parameters for BCH

Transport block size	246 bits+1bit (*)
CRC	16 bits
Coding	CC, coding rate = 1/3 This has to be included in table 1 in 25.222 4.2.3.
Π	20 ms
Midamble	144 chips
Codes and time slots	SF = 16 2 codes x 1 time slot
TFCI	0 bit
L1 control signals	0 bit

Note: The example is applied to BCH without multiplexing PCH and FACH.

\*: 1 extra bit in transport block is used for BCH indication.

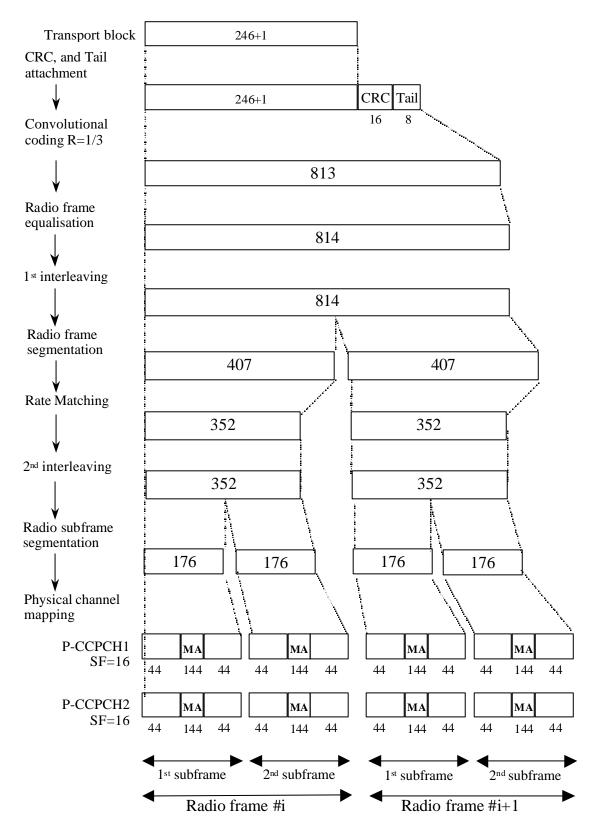

Figure B.1 Service mapping for BCH

#### B.2 2.4kbps data for downlink

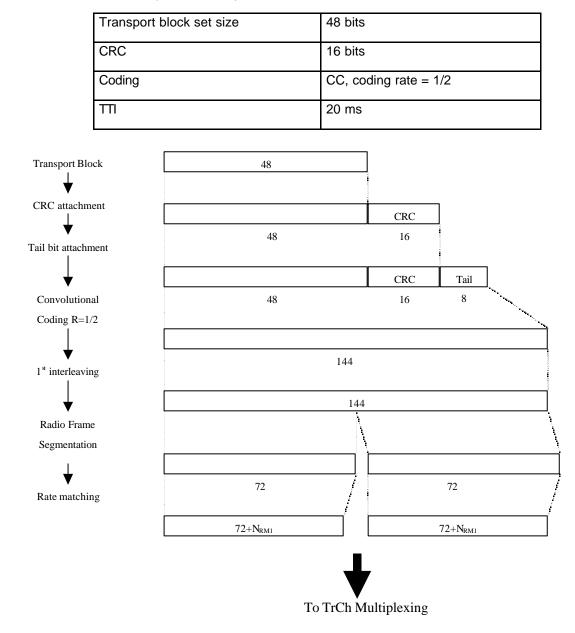

Table B.2 Parameter examples for 2.4kbps data

Figure B.2 Channel coding for 2.4kbps data

#### B.3 12.2kbps data for downlink

Note: this example can be applied to AMR speech

Number of TrChs	3
Transport block size	81bits(TrCh#1)
	103bits(TrCh#2)
	60bits(TrCh#3)
CRC	12(Only for TrCh#1)
Coding	CC, coding rate = 1/2, class B, C
	CC, coding rate = 1/3, class A
ΤП	20 ms
Midamble	144 chips
Codes and time slots	SF = 16
	2 codes x 1 time slots
TFCI	16bits (8 bits in each subframe)
L1control signals	4bits

Table B.3 Parameter examples for 12.2kbps data
