## 1. SUMMARY

This contribution provides text for a method of mapping arbitrary channel rays to discrete receiver samples for use in system simulations. This text is based on [1].

## 2. PROPOSED TEXT FOR RAY MAPPING

The following procedure is used to downsample the effective channel impulse response (including transmit and receive filters) for use with various discrete-time receiver algorithms. Figure 1 shows a block diagram of the effective continuous-time channel impulse response.

Figure 1. Continuous-time channel impulse response.

*Step 1: Produce a 1/16 chip sampled version of the combined transmit and receive filters.*

The convolution and sampling of the transmit and receive filters is shown in the equations below:

$$s(t) = s_{tx}(t) \otimes s_{rx}(t),$$

$$s(n) = s(nT_s),$$

where  $s(n)$  is the sampled version of the combined Tx-Rx filter,  $s(t)$  is the continuous time version of combined Tx-Rx filter, and  $T_s$  is the sampling interval of 1/16th of a chip.

*Step 2: Quantize the channel ray delays.*

Adjust the time delay of each ray produced by the SCM channel model to the nearest 1/16th chip interval,

$$n_l = \text{fix}\left(\frac{\tau_l}{T_s} + 0.5\right),$$

where  $\tau_l$  is the continuous-time delay of the  $l$ -th ray, and  $n_l$  is the quantized delay in 1/16 chip samples of the  $l$ -th ray.

*Step 3: Produce samples of the effective channel impulse response.*

Based on the quantized transmit filter, the received samples can be expressed as:

$$g(m) = \sum_{l=1}^L h_l \cdot s(M \cdot m - n_l),$$

where  $g$  is the decimated version of the effective channel impulse response,  $M$  is the decimation factor ( $M=16$  corresponds to chip spaced receiver sampling),  $s$  is the discrete-time version of the transmit filter sampled at 16 samples per chip, and  $h_l$  is the complex amplitude of the  $l$ -th ray. Figure 2 graphically represents the procedure.

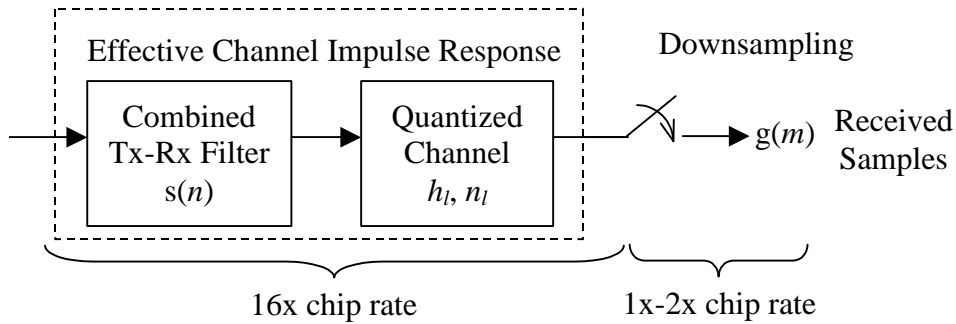

Figure 2. Channel impulse response with sampling.

Note that the final impulse response can be sampled at a rate of 1 or 2 samples per chip, depending on the receiver implementation.

### 3. CONCLUSIONS

Text was presented on an efficient channel impulse response sampling method that can be seen as a generalization of the methods of [2] and [3], allowing fractionally spaced equalizers and arbitrary choices of transmit and receive filters, while faithfully representing the spatial and temporal characteristics of the channel.
