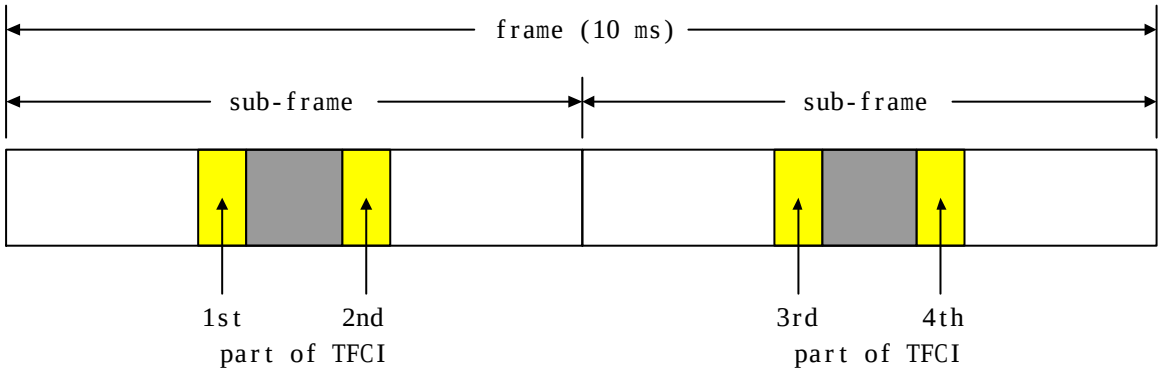
Title: Correction of the Mapping of TFCI Code Word for Very Short TFCI for 8PSK

Document for: Discussion and Approval

Discussion

In 1.28 Mcps TDD, QPSK and 8PSK may be used as modulation schemes. When QPSK is used each symbol represents 2 bits, and when 8PSK is used each symbol represents 3 bits. When the number of TFCI bit is 1, the coding scheme in the current Working CR to TS 25.222 produce 4 bit TFCI code word for QPSK, and 6 bit TFCI code word for 8PSK, respectively [1]. Thus, the TFCI code word corresponds to two symbols regardless of the modulation scheme used when the TFCI bit is 1.

In 1.28 Mcps TDD, a radio frame consists of two sub-frames and the TFCI code word is divided into 4 sub-parts to be transmitted before and after the midambles of the two consecutive sub-frames.



Four parts of TFCI code word in the radio frame

When the TFCI bit is 1, the coded TFCI word corresponds to only two symbols, which cannot be divided into 4 sub-parts. When QPSK modulation is used, the 4 bit TFCI code word is divided into 2 sub-parts instead of 4, each part corresponding one symbol, and are mapped onto the 1st and 3rd part of TFCI fields in the 1.28 Mcps frame structure [1]. In the description of the mapping of TFCI code word for 8PSK modulation, however, this fact is not taken into account. In this contribution, we propose to use the same mapping scheme for 1 bit TFCI. The following is the proposed correction of the Working CR.

4.4.2 Coding of transport format combination indicator (TFCI) for 8PSK

Encoding of TFCI bits depends on the number of them and the modulation in use. When 2 Mcps service is transmitted, 8PSK modulation is applied in 1.28 Mcps TDD option. The coding scheme for TFCI when the number of bits are 6 – 10, and less than 6 are described in section 4.4.2.1 and 4.4.2.2, respectively.

4.4.2.1 Coding of long TFCI lengths

When the number of TFCI bits are 6 – 10, the TFCI bits are encoded by using a (64,10) sub-code of the second order Reed-Muller code, then 16 bits out of 64 bits are punctured (Puncturing positions are 0, 4, 8, 13, 16, 20, 27, 31, 34, 38, 41, 44, 50, 54, 57, 61st bits). The coding procedure is shown in Figure [F1].

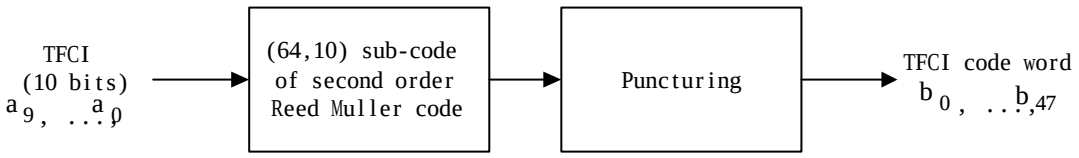

Figure [F1]: Channel coding of long TFCI bits for 8PSK

The code words of the punctured (48,10) sub-code of the second order Reed-Muller codes are linear combination of 10 basis sequences. The basis sequences are shown in Table [T1].

Table [T1]: Basis sequences for (48,10) TFCI code

47	1	1	1	1	1	1	1	1	0	0

Let's define the TFCI information bits as a_0 , a_1 , a_2 , a_3 , a_4 , a_5 , a_6 , a_7 , a_8 , a_9, where a_0 is the LSB and a_9 is the MSB. The TFCI information bits shall correspond to the TFC index (expressed in unsigned binary form) defined by the RRC layer to reference the TFC of the CCTrCH in the associated DPCH radio frame.

The output code word bits b_i are given by:

$$b_i = \sum_{n=0}^{9} (a_n \cdot M_{i,n}) \bmod 2$$

where i=0…47. N_{TFCI}=48.

4.4.2.2 Coding of short TFCI lengths

4.4.2.2.1 Coding very short TFCIs by repetition

When the number of TFCI bits is 1 or 2, then repetition will be used for the coding. In this case, each bit is repeated to a total of 6 times giving 6-bit transmission (N_{TFCI} = 6) for a single TFCI bit and 12-bit transmission (N_{TFCI} = 12) for 2 TFCI bits. For a single TFCI bit b_0, the TFCI code word shall be $\{b_0, b_0, b_0, b_0, b_0, b_0\}$. For TFCI bits b_0 and b_1, the TFCI code word shall be $\{b_0, b_1, b_0, b_1, b_0, b_1, b_0, b_1, b_0, b_1, b_0, b_1\}$.

4.4.2.2.2 Coding short TFCIs using bi-orthogonal codes

If the number of TFCI bits are in the range of 3 to 5, the TFCI bits are encoded using a (32,5) first order Reed-Muller code, then 8 bits out of 32 bits are punctured (Puncturing positions are 0, 1, 2, 3, 4, 5, 6, 7^{th} bits). The coding procedure is shown in Figure [F2].

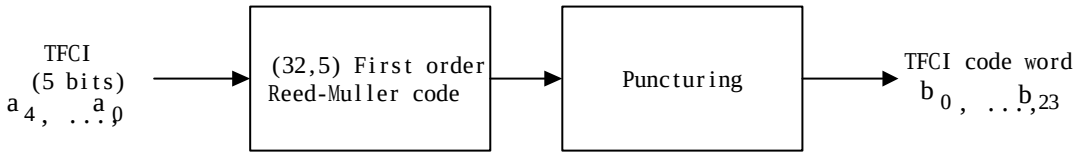

Figure [F2]: Channel coding of short TFCI bits for 8PSK

The code words of the punctured (32,5) first order Reed-Muller codes are linear combination of 5 basis sequences shown in Table [T2].

Table [T2]: Basis sequences for (24,5) TFCI code

I	$M_{i,0}$	$M_{i,1}$	$M_{i,2}$	$M_{i,3}$	$M_{i,4}$
0	0	0	0	1	0
1	1	0	0	1	0
2	0	1	0	1	0
3	1	1	0	1	0
4	0	0	1	1	0
5	1	0	1	1	0
6	0	1	1	1	0
7	1	1	1	1	0
8	0	0	0	0	1
9	1	0	0	0	1
10	0	1	0	0	1
11	1	1	0	0	1
12	0	0	1	0	1
13	1	0	1	0	1
14	0	1	1	0	1
15	1	1	1	0	1
16	0	0	0	1	1
17	1	0	0	1	1
18	0	1	0	1	1
19	1	1	0	1	1
20	0	0	1	1	1
21	1	0	1	1	1
22	0	1	1	1	1
23	1	1	1	1	1

Let's define the TFCI information bits as a_0 , a_1 , a_2 , a_3 , a_4, where a_0 is the LSB and a_4 is the MSB. The TFCI information bits shall correspond to the TFC index (expressed in unsigned binary form) defined by the RRC layer to reference the TFC of the CCTrCH in the associated DPCH radio frame.

The output code word bits b_i are given by:

$$b_i = \sum_{n=0}^{4} (a_n \cdot M_{i,n}) \bmod 2$$

where i=0…23. N_{TFCI}=24.

4.4.2.3 Mapping of TFCI word

Denote the number of bits in the TFCI word by N_{TFCI}, and denote the code word bits by b_k, where k = 0, …, N_{TFCI}-1.

When the number of bits in the TFCI code word is 12, 24, or 48, ~~The~~ the mapping of the TFCI word to the TFCI bit positions in a time slot shall be as follows.

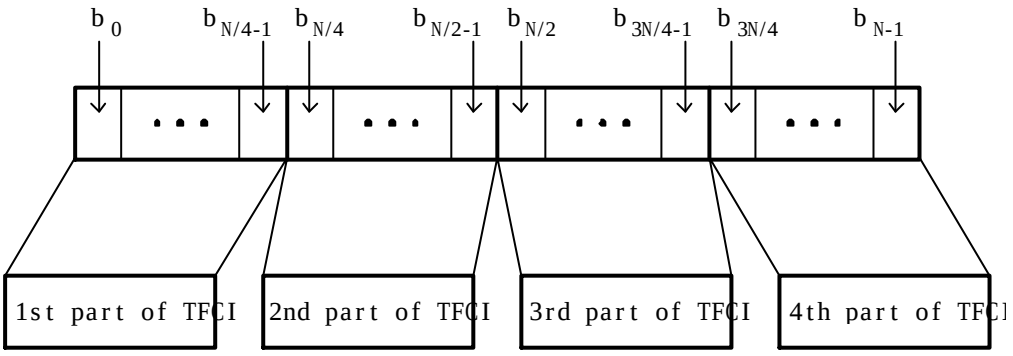

Figure [F3]: Mapping of TFCI word bits to timeslot in 1.28 Mcps TDD option, where N = N_{TFCI}.

When the number of bits in the TFCI code word is 8, the TFCI code word is equally divided into two parts for the consequtive two sub-frames and mapped onto the first data field in each of the consecutive sub-frames. The mapping of the TFCI code word to the TFCI bit positions in a time slot shall be as shown in figure [F4].

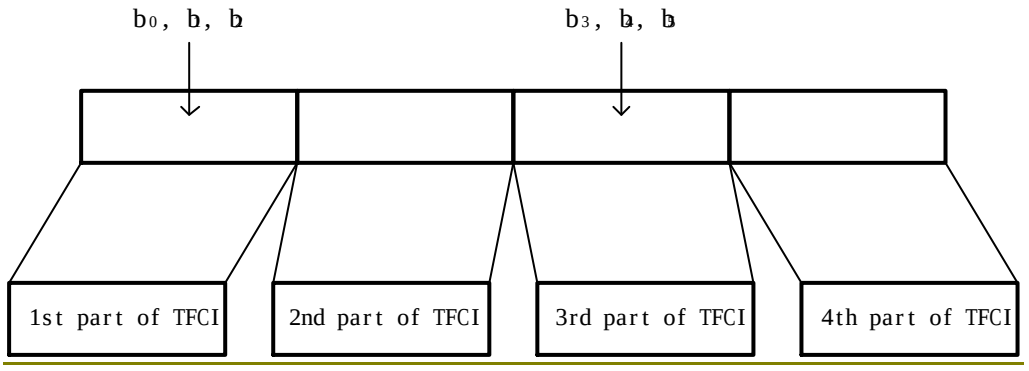

Figure [F4]: Mapping of TFCI word bits to timeslot in 1.28 Mcps TDD option when N_{TFCI} = 6

The location of the 1st to 4th parts of TFCI in the timeslot is defined in [7].
