How to create CRs using this form:

Comprehensive information and tips about how to create CRs can be found at: http://www.3gpp.org/3G_Specs/CRs.htm. Below is a brief summary:

- 1) Fill out the above form. The symbols above marked ⚡ contain pop-up help information about the field that they are closest to.
- 2) Obtain the latest version for the release of the specification to which the change is proposed. Use the MS Word "revision marks" feature (also known as "track changes") when making the changes. All 3GPP specifications can be downloaded from the 3GPP server under <ftp://www.3gpp.org/specs/> For the latest version, look for the directory name with the latest date e.g. 2000-09 contains the specifications resulting from the September 2000 TSG meetings.

4.2 Transport channel coding/multiplexing

Figure 1 illustrates the overall concept of transport-channel coding and multiplexing. Data arrives to the coding/multiplexing unit in form of transport block sets, once every transmission time interval. The transmission time interval is transport-channel specific from the set {10 ms, 20 ms, 40 ms, 80 ms}.

The following coding/multiplexing steps can be identified:

- add CRC to each transport block (see subclause 4.2.1);
- TrBk concatenation / Code block segmentation (see subclause 4.2.2);
- channel coding (see subclause 4.2.3);
- radio frame size equalization (see subclause 4.2.4);
- interleaving (two steps, see subclauses 4.2.5 and 4.2.10);
- radio frame segmentation (see subclause 4.2.6);
- rate matching (see subclause 4.2.7);
- multiplexing of transport channels (see subclause 4.2.8);
- physical channel segmentation (see subclause 4.2.9);
- sub-frame segmentation(see subclause 4.2.11 only for 1.28Mcps TDD)
- mapping to physical channels (see subclause 4.2.~~11~~12).

The coding/multiplexing steps for uplink and downlink are shown in figures [1](#) and [2](#).

Figure 1: Transport channel multiplexing structure for uplink and downlink [for 3.84Mcps TDD](#)

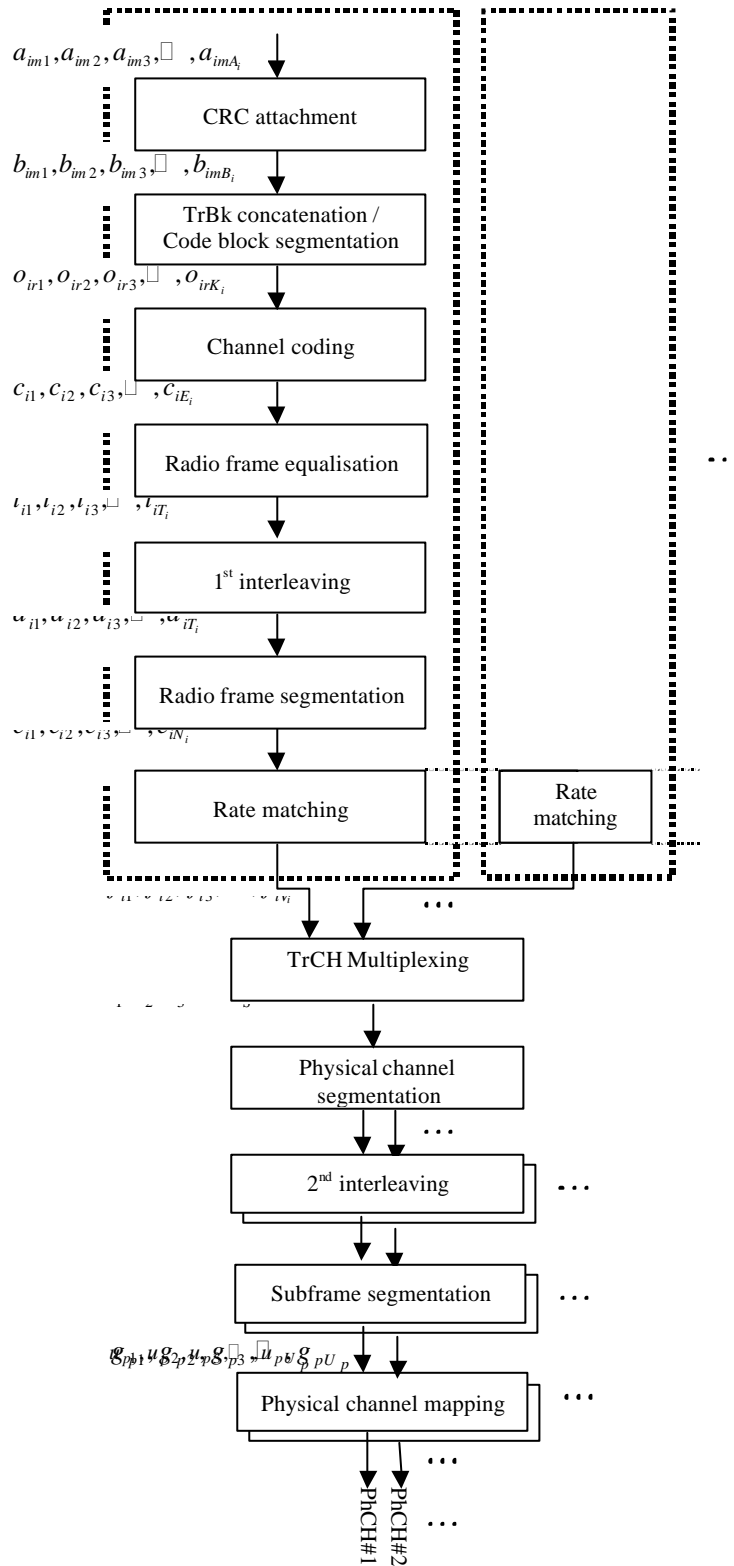

Figure 2: Transport channel multiplexing structure for uplink and downlink of 1.28Mcps TDD

Primarily, transport channels are multiplexed as described above, i.e. into one data stream mapped on one or several physical channels. However, an alternative way of multiplexing services is to use multiple CCTrCHs (Coded Composite Transport Channels), which corresponds to having several parallel multiplexing chains as in figures 1 and 2, resulting in several data streams, each mapped to one or several physical channels.

4.2.3 Channel coding

Code blocks are delivered to the channel coding block. They are denoted by $O_{ir1}, O_{ir2}, O_{ir3}, \dots, O_{irK_i}$, where i is the TrCH number, r is the code block number, and K_i is the number of bits in each code block. The number of code blocks on TrCH i is denoted by C_i . After encoding the bits are denoted by $y_{ir1}, y_{ir2}, y_{ir3}, \dots, y_{irY_i}$, where Y_i is the number of encoded bits. The relation between O_{irk} and y_{irk} and between K_i and Y_i is dependent on the channel coding scheme.

The following channel coding schemes can be applied to transport channels:

- convolutional coding;
- turbo coding;
- no coding.

Usage of coding scheme and coding rate for the different types of TrCH is shown in tables 1 and 2. The values of Y_i in connection with each coding scheme:

- convolutional coding with rate 1/2: $Y_i = 2 * K_i + 16$; rate 1/3: $Y_i = 3 * K_i + 24$;
- turbo coding with rate 1/3: $Y_i = 3 * K_i + 12$;
- no coding: $Y_i = K_i$.

Table 1: Usage of channel coding scheme and coding rate for 3.84Mcps TDD

Type of TrCH	Coding scheme	Coding rate
BCH	Convolutional coding	1/2
PCH		
RACH		
DCH, DSCH, FACH, USCH	Turbo coding	1/3, 1/2
		1/3
	No coding	

Table 2: Usage of channel coding scheme and coding rate for 1.28Mcps TDD

Type of TrCH	Coding scheme	Coding rate
BCH	Convolutional coding	1/3
PCH		1/3, 1/2
RACH		1/2
DCH, DSCH, FACH, USCH	Turbo coding	1/3, 1/2
		1/3
	No coding	

4.2.11 Sub-frame segmentation for the 1.28 Mcps option

In the 1.28Mcps TDD, it is needed to add a sub-frame segmentation unit between 2nd interleaving unit and physical channel mapping unit. The operation of rate-matching guarantees that the bit streams is a even number and can be subdivided into 2 sub-frames. The transport channel multiplexing structure for uplink and downlink is shown in figure 2.

The input bit sequence is denoted by $x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$ where i is the TrCH number and X_i is the number bits.

The two output bit sequences per radio frame are denoted by $y_{i,n_i1}, y_{i,n_i2}, y_{i,n_i3}, \dots, y_{i,n_iY_i}$ where n_i is the sub-frame number in current radio frame and Y_i is the number of bits per radio frame for TrCH i . The output sequences are defined as follows:

$$y_{i,n_i k} = x_{i, n_i \cdot 2 + k}, n_i = 1 \text{ or } 2, k = 1 \dots Y_i$$

where

$Y_i = (X_i / 2)$ is the number of bits per sub-frame.

x_{ik} is the k^{th} bit of the input bit sequence and

$y_{i,n_i k}$ is the k^{th} bit of the output bit sequence corresponding to the n^{th} sub-frame

The input bit sequence to the sub-frame segmentation is denoted by $v_{(t)1}, v_{(t)2}, \dots, v_{(t)U(t)}$, $X_k = v_{(t)k}$ and $X_i = U(t)$.

The output bit sequence corresponding to subframe n_i is denoted by $g_{p1}, g_{p2}, \dots, g_{pU_p}$, where p is the PhCH number and U_p is the number of bits in one subframe for the respective PhCH. Hence, $g_{pk} = y_{i,n_i k}$ and $U_p = Y_i$.

[4.2.12 Physical channel mapping](#)

~~4.2.11~~ [4.2.12.1 Physical channel mapping for the 3.84 Mcps option](#)

4.2.12.2 Physical channel mapping for the 1.28 Mcps option

The bit streams from the sub-frame segmentation unit are mapped onto code channels of time slots in sub-frames.

The bits after physical channel mapping are denoted by $W_{p1}, W_{p2}, \dots, W_{pU_p}$, where p is the PhCH number and U_p is the number of bits in one sub-frame for the respective PhCH. The bits w_{pk} are mapped to the PhCHs so that the bits for each PhCH are transmitted over the air in ascending order with respect to k .

The mapping of the bits $g_{p1}, g_{p2}, \dots, g_{pU_p}$ is performed like block interleaving, writing the bits into columns, but a PhCH with an odd number is filled in forward order, were as a PhCH with an even number is filled in reverse order.

The mapping scheme, as described in the following subclause, shall be applied individually for each timeslot t used

in the current subframe. Therefore, the bits $g_{p1}, g_{p2}, \dots, g_{pU_p}$ are assigned to the bits of the physical channels $W_{t1,1\dots U_{p1}}, W_{t2,1\dots U_{p2}}, \dots, W_{tP_t,1\dots U_{p_{P_t}}}$ in each timeslot.

In uplink there are at most two codes allocated ($P \leq 2$). If there is only one code, the same mapping as for downlink is applied. Denote SF1 and SF2 the spreading factors used for code 1 and 2, respectively. For the number of consecutive bits to assign per code bs_k the following rule is applied:

if

SF1 \geq SF2 then $bs_1 = 1$; $bs_2 = SF1/SF2$;

else

SF2 $>$ SF1 then $bs_1 = SF2/SF1$; $bs_2 = 1$;

end if

In the downlink case bs_p is 1 for all physical channels.

4.2.12.2.1 Mapping scheme

Notation used in this subclause:

P_t : number of physical channels for timeslot t , $P_t = 1, 2$ for uplink ; $P_t = 1 \dots 16$ for downlink

U_{pt} : capacity in bits for the physical channel p in timeslot t

U_t : total number of bits to be assigned for timeslot t

bs_p : number of consecutive bits to assign per code

for downlink all $bs_p = 1$

for uplink if SF1 \geq SF2 then $bs_1 = 1$; $bs_2 = SF1/SF2$;

if SF2 $>$ SF1 then $bs_1 = SF2/SF1$; $bs_2 = 1$;

fb_p : number of already written bits for each code

pos : intermediate calculation variable

for $p=1$ to P_t -- reset number of already written bits for every physical channel

$fb_p = 0$

end for

$p = 1$ -- start with PhCH #1

```
for k=1 to Ur
do while (fbp == Ur,p) -- physical channel filled up already ?
p = (p mod Pr) + 1 ;
end do
if (p mod 2) == 0
pos = Ur,p - fbp -- reverse order
else
pos = fbp + 1 -- forward order
end if
wp,pos = gt,k -- assignment
fbp = fbp + 1 -- Increment number of already written bits
If (fbp mod bs,p) == 0 -- Conditional change to the next physical channel
p = (p mod Pt) + 1 ;
end if
end for
```

4.2.4213 Multiplexing of different transport channels onto one CCTrCH, and mapping of one CCTrCH onto physical channels

Different transport channels can be encoded and multiplexed together into one Coded Composite Transport Channel (CCTrCH). The following rules shall apply to the different transport channels which are part of the same CCTrCH:

- 1) Transport channels multiplexed into one CCTrCh shall have co-ordinated timings. When the TFCS of a CCTrCH is changed because one or more transport channels are added to the CCTrCH or reconfigured within the CCTrCH, or removed from the CCTrCH, the change may only be made at the start of a radio frame with CFN fulfilling the relation

$$\text{CFN mod } F_{\max} = 0,$$

where F_{\max} denotes the maximum number of radio frames within the transmission time intervals of all transport channels which are multiplexed into the same CCTrCH, including any transport channels i which are added reconfigured or have been removed, and CFN denotes the connection frame number of the first radio frame of the changed CCTrCH.

After addition or reconfiguration of a transport channel i within a CCTrCH, the TTI of transport channel i may only start in radio frames with CFN fulfilling the relation

$$\text{CFN}_i \text{ mod } F_i = 0.$$

- 2) Different CCTrCHs cannot be mapped onto the same physical channel.
- 3) One CCTrCH shall be mapped onto one or several physical channels.
- 4) Dedicated Transport channels and common transport channels cannot be multiplexed into the same CCTrCH.
- 5) For the common transport channels, only the FACH and PCH may belong to the same CCTrCH.
- 6) Each CCTrCH carrying a BCH shall carry only one BCH and shall not carry any other Transport Channel.
- 7) Each CCTrCH carrying a RACH shall carry only one RACH and shall not carry any other Transport Channel.

Hence, there are two types of CCTrCH.

CCTrCH of dedicated type, corresponding to the result of coding and multiplexing of one or several DCH.

CCTrCH of common type, corresponding to the result of the coding and multiplexing of a common channel, i.e. RACH and USCH in the uplink and DSCH, BCH, FACH or PCH in the downlink, respectively.

Transmission of TFCI is possible for CCTrCH containing Transport Channels of:

- dedicated type;
- USCH type;
- DSCH type;
- FACH and/or PCH type.

4.2.4213.1 Allowed CCTrCH combinations for one UE

4.2.4213.1.1 Allowed CCTrCH combinations on the uplink

The following CCTrCH combinations for one UE are allowed, also simultaneously:

- 1) several CCTrCH of dedicated type;
- 2) several CCTrCH of common type.

4.2.~~42~~13.1.2 Allowed CcTTrCH combinations on the downlink

The following CcTTrCH combinations for one UE are allowed, also simultaneously:

- 3) several CcTTrCH of dedicated type;
- 4) several CcTTrCH of common type.

4.2.~~43~~14 Transport format detection

Transport format detection can be performed both with and without Transport Format Combination Indicator (TFCI). If a TFCI is transmitted, the receiver detects the transport format combination from the TFCI. When no TFCI is transmitted, so called blind transport format detection may be used, i.e. the receiver side uses the possible transport format combinations as a priori information.

4.2.~~43~~14.1 Blind transport format detection

Blind Transport Format Detection is optional both in the UE and the UTRAN. Therefore, for all CcTTrCH a TFCI shall be transmitted, including the possibility of a TFCI length zero, if only one TFC is defined.

4.2.~~43~~14.2 Explicit transport format detection based on TFCI

4.2.~~43~~14.2.1 Transport Format Combination Indicator (TFCI)

The Transport Format Combination Indicator (TFCI) informs the receiver of the transport format combination of the CcTTrCHs. As soon as the TFCI is detected, the transport format combination, and hence the individual transport channels' transport formats are known, and decoding of the transport channels can be performed.

4.3 Coding for layer 1 control [for the 3.84 Mcps option](#)

4.4 Coding for layer 1 control for the 1.28 Mcps option

4.4.1 Coding of transport format combination indicator (TFCI) for QPSK

The coding of TFCI for 1.28Mcps TDD is same as that of 3.84Mcps TDD.cf.[4.3.1 ‘Coding of transport format combination indicator’].

4.4.1.1 Mapping of TFCI word

Denote the number of bits in the TFCI word by N_{TFCI} , and denote the code word bits by b_k , where $k = 0, \dots, N_{TFCI}-1$

When the number of bits in the TFCI is 8,16,32, the mapping of the TFCI word to the TFCI bit positions shall be as follows.

Figure [9]: Mapping of TFCI word bits to TFCI position in 1.28 Mcps TDD option, where $N = N_{TFCI}$

When the number of bits in the TFCI is 4, then the TFCI word is equally divided into two parts for the consecutive two subframe and mapped onto the end of the first data field in each of the consecutive subframes.The mapping for $N_{TFCI}=4$ is show in figure [10]:

Figure [10]: Mapping of TFCI word bits to TFCI position in 1.28 Mcps TDD option, when $N_{TFCI}=4$

The location of the 1st to 4th parts of TFCI in the timeslot is defined in [7].

If the shortest transmission time interval of any constituent TrCH is at least 20 ms the successive TFCI words in the frames in the TTI shall be identical. If TFCI is transmitted on multiple timeslots in a frame each timeslot shall have the same TFCI word.

4.4.2 Coding of transport format combination indicator (TFCI) for 8PSK

Encoding of TFCI bits depends on the number of them and the modulation in use. When 2 Mcps service is transmitted, 8PSK modulation is applied in 1.28 Mcps TDD option. The coding scheme for TFCI when the number of bits are 6–10, and less than 6 are described in section 4.4.2.1 and 4.4.2.2, respectively.

4.4.2.1 Coding of long TFCI lengths

When the number of TFCI bits are 6–10, the TFCI bits are encoded by using a (64,10) sub-code of the second order Reed-Muller code, then 16 bits out of 64 bits are punctured (Puncturing positions are 0, 4, 8, 13, 16, 20, 27, 31, 34, 38, 41, 44, 50, 54, 57, 61st bits). The coding procedure is shown in Figure [11].

Figure [11]: Channel coding of long TFCI bits for 8PSK

The code words of the punctured (48,10) sub-code of the second order Reed-Muller codes are linear combination of 10 basis sequences. The basis sequences are shown in Table [12].

Table [12]: Basis sequences for (48,10) TFCI code

<u>43</u>	<u>0</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>0</u>
<u>44</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>0</u>
<u>45</u>	<u>0</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>
<u>46</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>0</u>	<u>1</u>
<u>47</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>0</u>

Let's define the TFCI bits as $a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9$, where a_0 is the LSB and a_9 is the MSB. The TFCI bits shall correspond to the TFC index (expressed in unsigned binary form) defined by the RRC layer to reference the TFC of the CCTrCH in the associated DPCH radio frame.

The output code word bits b_i are given by:

$$b_i = \sum_{n=0}^9 (a_n \cdot M_{i,n}) \text{ mod } 2$$

where $i=0 \dots 47$, $N_{\text{TFCI}}=48$.

4.4.2.2 Coding of short TFCI lengths

4.4.2.2.1 Coding very short TFCIs by repetition

When the number of TFCI bits is 1 or 2, then repetition will be used for the coding. In this case, each bit is repeated to a total of 6 times giving 6-bit transmission ($N_{\text{TFCI}}=6$) for a single TFCI bit and 12-bit transmission ($N_{\text{TFCI}}=12$) for 2 TFCI bits. For a single TFCI bit b_0 , the TFCI code word shall be $\{b_0, b_0, b_0, b_0, b_0, b_0\}$. For TFCI bits b_0 and b_1 , the TFCI code word shall be $\{b_0, b_1, b_0, b_1, b_0, b_1, b_0, b_1, b_0, b_1, b_0, b_1\}$.

4.4.2.2.2 Coding short TFCIs using bi-orthogonal codes

If the number of TFCI bits is in the range of 3 to 5, the TFCI bits are encoded using a (32,5) first order Reed-Muller code, then 8 bits out of 32 bits are punctured (Puncturing positions are 0, 1, 2, 3, 4, 5, 6, 7th bits). The coding procedure is shown in Figure [12].

Figure [12]: Channel coding of short TFCI bits for 8PSK

The code words of the punctured (32,5) first order Reed-Muller codes are linear combination of 5 basis sequences shown in Table [13].

Table [13]: Basis sequences for (24,5) TFCI code

<u>l</u>	<u>M_{i,0}</u>	<u>M_{i,1}</u>	<u>M_{i,2}</u>	<u>M_{i,3}</u>	<u>M_{i,4}</u>

<u>4</u>	<u>0</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>0</u>
<u>5</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>0</u>
<u>6</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>
<u>7</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>
<u>8</u>	<u>0</u>	<u>0</u>	<u>0</u>	<u>0</u>	<u>1</u>
<u>9</u>	<u>1</u>	<u>0</u>	<u>0</u>	<u>0</u>	<u>1</u>
<u>10</u>	<u>0</u>	<u>1</u>	<u>0</u>	<u>0</u>	<u>1</u>
<u>11</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>0</u>	<u>1</u>
<u>12</u>	<u>0</u>	<u>0</u>	<u>1</u>	<u>0</u>	<u>1</u>
<u>13</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>0</u>	<u>1</u>
<u>14</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>
<u>15</u>	<u>1</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>
<u>16</u>	<u>0</u>	<u>0</u>	<u>0</u>	<u>1</u>	<u>1</u>
<u>17</u>	<u>1</u>	<u>0</u>	<u>0</u>	<u>1</u>	<u>1</u>
<u>18</u>	<u>0</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>
<u>19</u>	<u>1</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>
<u>20</u>	<u>0</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>1</u>
<u>21</u>	<u>1</u>	<u>0</u>	<u>1</u>	<u>1</u>	<u>1</u>

22	0	1	1	1	1
23	1	1	1	1	1

Let's define the TFCI bits as a_0, a_1, a_2, a_3, a_4 , where a_0 is the LSB and a_4 is the MSB. The TFCI bits shall correspond to the TFC index (expressed in unsigned binary form) defined by the RRC layer to reference the TFC of the CCTrCH in the associated DPCH radio frame.

The output code word bits b_i are given by:

$$b_i = \left(\sum_{n=0}^4 a_n M_{i,n} \right) \bmod 2$$

where $i=0 \dots 23$, $N_{TFCI}=24$.

4.4.2.3 Mapping of TFCI code word

Denote the number of bits in the TFCI code word by N_{TFCI} , and denote the TFCI code word bits by b_k , where $k = 0, \dots, N_{TFCI}-1$.

When the number of bits in the TFCI code word is 12, 24, or 48, the mapping of the TFCI code word to the TFCI bit positions in a time slot shall be as follows.

Figure [13]: Mapping of TFCI code word bits to timeslot in 1.28 Mcps TDD option, where $N = N_{TFCI}$.

When the number of bits in the TFCI code word is 6, the TFCI code word is equally divided into two parts for the consecutive two sub-frames and mapped onto the first data field in each of the consecutive sub-frames. The mapping of the TFCI code word to the TFCI bit positions in a time slot shall be as shown in figure [14].

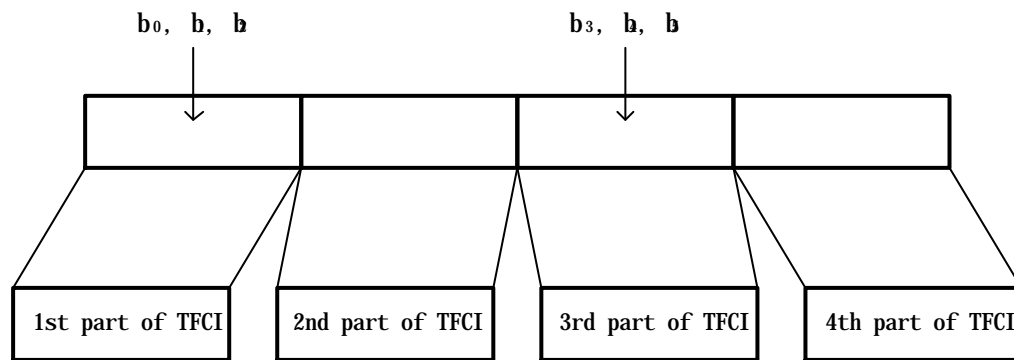

Figure [14]: Mapping of TFCI code word bits to timeslot in 1.28 Mcps TDD option when $N_{TFCI} = 6$

The location of the 1st to 4th parts of TFCI in the timeslot is defined in [7].

4.4.3 Coding of the Forward Physical Access Channel (FPACH) information bits

The FPACH burst is composed by 32 information bits which are block coded and convolutional coded, and then delivered in one sub-frame as follows:

1. The 32 information bits are protected by 8 parity bits for error detection as described in sub-clause 4.2.1.1.
2. Convolutional code with constraint length 9 and coding rate $\frac{1}{2}$ is applied as described in sub-clause 4.2.3.1. The size of data block $c(k)$ after convolutional encoder is 96 bits.
3. To adjust the size of the data block $c(k)$ to the size of the FPACH burst, 8 bits are punctured as described in sub-clause 4.2.7 with the following clarifications:

?? $N_{i,j} = 96$ is the number of bits in a radio sub-frame before rate matching

?? $N_{i,j} = 8$ is the number of bits to punctured in a radio sub-frame

?? $e_{ini} = a \times N_{i,j}$

The 88 bits after rate matching are then delivered to the intra-frame interleaving.

4. The bits in input to the interleaving unit are denoted as $\{x(0), \dots, x(87)\}$. The coded bits are block rectangular interleaved according to the following rule: the input is written row by row, the output is read column by column.

?	$x(0)$	$x(1)$	$x(2)$	□	$x(7)$?
?	$x(8)$	$x(9)$	$x(10)$	□	$x(15)$?
?	□	□	□	□	□	?
?	$x(80)$	$x(81)$	$x(82)$	□	$x(87)$?

Hence, the interleaved sequence is denoted by $y(i)$ and are given by:

$y(0), y(1), \dots, y(87) = x(0), x(8), \dots, x(80), x(1), \dots, x(87)$.
